AUTHOR'S PREFACE.

———

THIS English edition of my "Anleitung zur quantitativen Bestimmung der organischen Atomgruppen" has been prepared by Dr. J. Bishop Tingle, to whom I am greatly indebted for the care he has bestowed on it.   I have endeavored to bring it into conformity with the present state of the science by various corrections and additions.   It has been further improved by certain changes in arrangement which Dr. Tingle has made, and he has also added various notes.   The present edition is thus a decided advancement on the German one, and I trust that in its new form it may gain many new friends whilst retaining its old ones.

Dr. HANS MEYER.

TRANSLATOR'S PREFACE.

THE success of the German edition of Dr. Meyer's book was only one of the reasons that led to the preparation of this translation. The quantitative side of organic chemistry, apart from elementary analysis, is almost always neglected in the ordinary courses of instruction, and when the need for it arises, in the prosecution of research work for instance, it is difficult to obtain a comprehensive view of the methods which are available without undue expenditure of time. This little work supplies, for the first time, a systematic treatment of these methods which, it is hoped, may help to remove this drawback and may also encourage the introduction of some *quantitative* work into the college courses of organic preparations, since such a departure could scarcely fail to be beneficial in various ways to the student. From the translator's experience with the German edition he believes that the present one will be serviceable to instructors and senior students of organic chemistry. Considerable care has been bestowed on the proof-sheets, and it is hoped that the errors which may have escaped notice are not too glaring.

DETERMINATION OF RADICLES IN CARBON COMPOUNDS.

CHAPTER I.

INTRODUCTORY. DETERMINATION OF HYDROXYL (-OH).

THE quantitative analysis of inorganic compounds, as usually performed, consists almost exclusively in the determination of ions, since in the present state of the science this generally suffices for the identification of the substance; but to attain the same end in the case of organic bodies the elementary analysis requires supplementing by other methods. The percentage composition gives no information about the relative arrangement of the atoms in the molecule, but the demand for methods of analysis which will yield such knowledge increases with our growing insight into the constitution of carbon compounds. To supply this want certain "quantitative reactions" have been applied for the determination of special groups of atoms; they are widely, but almost exclusively, employed by technologists in the analysis of such substances as fats, waxes, resins, ethereal oils, caoutchouc, glue, paper, etc., and the results are

known as the "acid number," "saponification number," "iodine number," "methoxyl number," "acetyl number," "carbonyl number," etc. The determination of such "numbers" or "values" obtained by the action of some reagent on a known weight of substance is frequently insufficient for scientific investigation, this renders it necessary to work out a special process for each group of organic compounds in order to determine the radicles which are present.

The reactions of organic compounds are only in part ionic; usually they are conditioned by the configuration and state of equilibrium of the molecule, and consequently a reaction which readily occurs with one compound may totally fail with another of very similar constitution on account of stereoisomerism; or, by substitution, a radicle may approximate more or less closely to the character and functions of another one. In these cases the quantitative separation of the compounds is more difficult, and can frequently only be accomplished by differences in crystallizing power, or by the preparation of derivatives which can be volatilized without decomposition.

Since the course of a particular reaction of an inorganic compound is only conditioned by the behavior of the ions which are to be determined, it follows that the analytical methods are in a sense independent of the nature of the compounds investigated, and consequently of very wide application. The matter is far otherwise with organic compounds: there are very few processes which, like Ziesel's method for determining methoxyl, can be applied almost universally.

Usually, then, it becomes necessary for the analyst himself to select the method most appropriate for his special purpose, or, perhaps by a combination of several, to devise one which may lead to the desired result. The successful methods hitherto proposed for the determination of organic radicles have been collected together in this work, and it is hoped that they may serve to indicate the direction in which research may be successfully prosecuted for the discovery of new ones applicable to hitherto unforeseen conditions.

DETERMINATION OF HYDROXYL (-ȮH).

The determination of the hydroxyl radicle in organic compounds consists in the preparation of derivatives by the following methods:

(I.) ACYLATION.—This consists in the introduction into the hydroxyl compound of the radicle of one of the acids mentioned below:

Acetic acid;

Benzoic acid and its substitution products;

Phenylsulphonic acid.

Of less frequent employment are the radicles of

Propionic acid;

Isobutyric acid;

Phenylacetic acid.

(II.) ALKYLATION.—Confined usually to the preparation of *benzyl* derivatives.

(III.) The preparation of CARBAMATES.

(IV.) The formation of ESTERS OF PHENYLCARBAMIC ACID.

As a rule, attention is first directed to the preparation of an acetyl or benzoyl derivative, the former usually by Liebermann & Hörmann's method (see page 7), the latter by that of Lossen or Schotten-Baumann (see page 18). Not infrequently, however, it becomes necessary to resort to one of the other forms of procedure in order to determine the constitution of the body under investigation. As the groups NH_2, NH_2 and SH are all capable of acylation, care is required to avoid confusion if the original compound contains nitrogen or sulphur. Instances are known of acetylation taking place in the absence of hydroxyl and of the groups just referred to, thus diacetylhydroquinol is formed from quinone, acetic anhydride, and sodium acetate;[1] tetrachloroquinone and acetyl chloride yield diacetyltetrachlorohydroquinol;[2] whilst pyrogallophthaleïn (galleïn), which contains only two hydroxyl groups, forms a tetracetyl and tetrabenzoyl derivative.[3] Acetylating reagents frequently cause isomerization or polymerization, and sometimes lead to the production of anhydrides, etc.; thus benzhydrylacetocarboxylican hydride is obtained from the isomeric orthocinnamocarboxylic acid by the action of acetic anhydride and sodium acetate,[4] and cantharic acid when heated in a sealed tube with acetyl chloride yields isocantharidin.[5] In view of these and similar facts, care should be taken to hydrolyse the presumptive acetyl derivative and identify the product with the original substance; should this

[1] Sarauw, B. 12, 680.   [2] Graebe, Ann. 146, 13.

[5] Anderlini and Ghiro, B. 24, 1998.

not be possible, then proof must be obtained that the derivative does actually contain the acid radicle, the introduction of which has been attempted.

I. METHODS OF ACETYLATION.

(1) PREPARATION OF ACETYL DERIVATIVES.

The following reagents are employed for the preparation of acetyl derivatives from organic compounds containing hydroxyl groups:

(A) *Acetyl chloride.*

(B) *Acetic anhydride, sodium acetate.*

(C) *Glacial acetic acid.*

(D) *Chloracetyl chloride.*

(A) Acetylation by Means of Acetyl Chloride.

(*a*) Many hydroxyl derivatives react with acetyl chloride when simply mixed or digested on the water-bath. It is convenient to dissolve the substance and the chloride in benzene, and boil the solution until the evolution of hydrochloric acid ceases. If there is no danger of the hydrogen chloride causing secondary reactions (hydrolysis), of which an interesting case has been recorded,[1] the substance may be heated with the chloride in a sealed tube without solvent. Certain dibasic hydroxy acids of the aliphatic series, such as mucic acid, which are not changed with acetyl chloride alone, frequently react with it on the addition of zinc chloride.[2] In general, it may be stated that acetyl

[1] Herzig and Schiff, B. 30, 397. Cf. Bamberger and Landsiedl, M. 18, 307.

[2] S. ... 258

chloride only reacts readily with alcohols and phenols, but, as it may lead to the production of anhydrides from polybasic acids, these are usually employed in the form of esters, which has the additional advantage of yielding products that are much more easily distilled than the corresponding derivatives of the acids themselves.[1]

(*b*) The following method[2] is frequently more convenient than the "acid" acetylation just described. The substance is dissolved in ether or benzene, and digested with the necessary quantity of acetyl chloride and dry alkali carbonate, the latter being in the proportion necessary to form a hydrogen salt as represented by the equation:

$$R.OH + CH_3.COCl + K_2CO_3 \longrightarrow R.O.CO.CH_3 + KCl + KHCO_3.$$
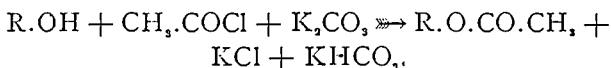

(*c*) Acetylation by means of acetyl chloride and aqueous alkali is described on p. 20.

(*d*) It is often convenient to allow the acetyl chloride to react with the compound under investigation in pyridine solution.[3]

(*e*) Diacetylacetone could only be acetylated by allowing its barium salt to react with acetyl chloride at the ordinary temperature.[4]

(*f*) Instead of acetyl chloride phosphorus trichloride, or preferably the oxychloride, or phosgene may be employed; they are allowed to react on a mixture of the substance and acetic acid in the proper propor-

[1] Wislicenus, Ann. **129**, 17.   [2] L. Claisen, B. **27**, 3182.
[3] A. Deninger, B. **28**, 1322.   [4] Feist, *Ibid.* **28**, 1824.

tion.' Thus, for example, phenol is readily acetylated by heating it at 80° with an equimolecular proportion of acetic acid and adding phosphorus oxychloride ($\frac{1}{3}$ molecule) gradually, by means of a dropping funnel. When hydrogen chloride is no longer evolved the product is poured into cold aqueous soda solution; after further washing with highly dilute alkali it is treated once with water, dried by means of calcium chloride, and distilled.

(B) Acetylation by Means of Acetic Anhydride.

(*a*) The substance is usually boiled with 5–10 parts of anhydride, or heated with it in a sealed tube during several hours.

(*b*) Not infrequently the substances must only be allowed to react during a short time, at a comparatively low temperature. Bebirine, for instance, is readily acetylated when digested with the anhydride during a short time at 40°–50°, but by its prolonged action amorphous substances are formed.[2]

(*c*) The substance may be mixed with an equal weight of dry sodium acetate, and 3–4 parts of the anhydride, and boiled for a short time in a reflux apparatus;[3] in the case of small quantities of substance 2–3 minutes boiling may suffice. The action appears to depend on the production of a sodium salt of the compound under examination, which then reacts with the anhydride. This method yields, on the whole, the most trustworthy results of any, and sel-

[1] J. pr. **25**, 282; **26**, 62; **31**, 467.   [2] B. **29**, 2057.

[3] C. Liebermann and O. Hörmann, *Ibid.* **11**, 1619.

dom fails to give completely acetylated derivatives.
It fails in the case of the α-hydroxyl of the hydroxy-
quinolines,[1] though these compounds yield benzoyl
derivatives.

(d) A mixture of acetic anhydride and acetyl
chloride may be used, or the action of the anhydride
may be started by means of a drop of concentrated
sulphuric acid.[2]

(e) The addition of zinc chloride[3] and of stannic
chloride[4] has also been recommended.

(C) Acetylation by Means of Glacial Acetic Acid.

Acetylation, especially that of alcoholic hydroxyl
groups, may often be accomplished by heating the
substance with glacial acetic acid, under pressure if
necessary; the addition of sodium acetate is also
advantageous, and, in some cases, this is the only
method which gives the desired result. Thus, cam-
phorpinacone yields a chloride when treated with
acetyl chloride, and is not changed by boiling acetic
anhydride, but when it is boiled with glacial acetic
acid for a short time, a stable acetyl derivative is
formed, and an isomeric "labile" one by the action
of the acid at the ordinary temperature during
twenty-four hours.[5]

(D) Acetylation by Means of Chloracetyl Chloride.

This reagent has also been employed occasionally,[6]

II. ISOLATION OF THE ACETYL DERIVATIVES.

Acetyl derivatives are isolated by pouring the product of the reaction into water. The excess of acetic acid may also be removed by the addition of methylic alcohol to convert it into methylic acetate, which is then volatilized; residual acetic anhydride is separated by distillation under reduced pressure. Acetyl derivatives, soluble in water, may often be precipitated by the addition of solid sodium carbonate, or by extracting the solution with chloroform or benzene. Ethylic acetate frequently proves to be an excellent medium for the subsequent recrystallization of the acetyl product.

III. DETERMINATION OF THE ACETYL GROUPS.

The various acetyl derivatives of a compound usually differ little in percentage composition, so that elementary analysis seldom affords information as to the number of acetyl groups which have entered the original molecule; thus, the mono-, di-, and tri-acetyl derivatives of the trihydroxybenzenes have an identical percentage composition. In such cases the acetyl groups must be eliminated and the acetic acid formed determined directly or indirectly.

(A) Hydrolytic Methods.

The following reagents are employed for the hydrolysis of acetyl compounds:

(*a*) *Water.*

(*b*) *Potassium hydroxide, sodium hydroxide.*

(*c*) *Barium hydroxide.*

(*d*) *Magnesia.*

(*e*) *Hydrochloric acid.*

(*f*) *Sulphuric acid.*

(*g*) *Hydriodic acid.*

(*a*) Some acetyl derivatives are hydrolysed by heating with water under pressure; thus butenyltriacetin, $C_4H_7(C_2H_3O_2)_3$, is completely hydrolysed by heating it with forty parts of water at 160° in a sealed tube, and the liberated acetic acid may be titrated.[1] Diacetylmorphine also loses one aceytl group by boiling it with water,[2] and acetyl dihydroxypyridine is still more unstable.[3]

(*b*) Hydrolysis by means of potassium hydroxide or sodium hydroxide is specially useful for the analysis of fats. The compound (1–2 grams) is gently boiled on the water-bath during fifteen minutes, in a wide-necked flask of 100–150 cc capacity, with alcoholic potash (25–50 cc) of known strength, which should be about $N/2$. During the heating the neck of the flask is covered with a cold funnel; at the conclusion of the hydrolysis phenolphthaleïn is added, and the excess of alkali determined by means of $N/2$ hydrochloric acid.[4] The method may also be employed for the determination of the molecular weight of the aliphatic alcohols. This is obtained

[3] M. **18**, 619.   [4] Benediki and Ulzer, M. **8**, 41.

from the expression $M = \dfrac{56100}{V} - 42$, where M is the
molecular weight, and V the number of milligrams of
potassium hydroxide required to hydrolyse 1 gram of
the acetyl derivative. If the compound is affected
by air, the hydrolysis is carried out in an atmos-
phere of hydrogen;[1] should the original compound
be insoluble in dilute hydrochloric acid, the acetyl
derivative may be boiled with aqueous potash, the
product acidified, and the precipitate weighed.[2]

(c) Barium hydroxide may be employed in many
cases where potash causes decomposition, thus
hæmatoxylin yields formic acid when boiled with
highly dilute alkali, but barium hydroxide readily
hydrolyses its acetyl derivatives without further
decomposition.[3] One method of procedure[4] is to
boil the compound under investigation with the
hydroxide during 5–6 hours in a reflux apparatus.
The product is filtered, the filtrate treated with car-
bonic anhydride in excess, again filtered, and the
filtrate evaporated. The residue is dissolved in
water, the liquid filtered, and, after washing, the
barium in the filtrate is determined as sulphate.
Since all the above operations are conducted in glass
vessels, some alkali from these may neutralize a por-
tion of the acetic acid and a correction thus becomes
necessary. This is obtained by concentrating the
filtrate from the barium sulphate in a platinum dish;

[1] Klobukowsky, B. 10, 882.

[2] Vortmann, "Anleitung zur chemischen Analyse organischer
Stoffe," p. 59.

[3] Erdmann and Schultz, Ann. 216, 234.   [4] Herzig, M. 5, 86.

when the excess of sulphuric acid has been volatilized, the residue is treated with pure ammonium carbonate until its weight becomes constant. It is now dissolved in water, the silica removed, and the sulphates in the filtrate determined as barium sulphate, the weight of which is added to that first found. If the hydrolysis, etc., can be carried out in vessels of silver,[1] the above correction is unnecessary. The action of the barium hydroxide solution is promoted by the previous addition to the substance of a few drops of alcohol.[2]

(d) Magnesia is generally employed in the following manner:[3] Ordinary "ignited magnesia," and the basic carbonate (magnesia alba) are both unsuitable, as they contain alkali carbonates which are difficult to remove. The magnesia is prepared from the sulphate or chloride, which must be free from iron: the solution is treated with alkali hydroxide in quantity insufficient to cause complete precipitation; after thorough washing the magnesia is retained as a paste under water. The acetyl derivative (1–1.5 grams) is intimately mixed with the magnesia paste (about 5 grams) and a little water, and transferred, together with water (100 cc), to a flask of resistant glass. The mixture is boiled in a reflux apparatus during 4–6 hours, although usually the hydrolysis is completed in 2–3 hours. The liquid is concentrated in the flask to a third of its original volume, cooled, filtered by means of a pump, the insoluble portion washed, and the filtrate and washings treated with ammonium

---

[1] Lieben and Zeisel, M. **4**, 42; **7**, 69.

[2] Barth and Goldschmiedt, B. **12**, 1237.

[3] H. Schiff, *Ibid.* **12**, 1531. Ann. **154**, 11.

chloride, ammonium hydrate, and ammoniacal sodium phosphate. The magnesium ammonium phosphate, after standing during twelve hours, is filtered, dissolved in dilute hydrochloric acid, and reprecipitated by means of ammonium hydrate; 1 part of $Mg_2P_2O_7 =$ 0.774648 parts of C_2H_4O. The solubility of magnesia in highly dilute solutions of magnesium acetate is too small to require a correction. Even "insoluble" acetyl derivatives may be hydrolysed by magnesia, provided that they are in a finely divided state, the boiling being prolonged to twelve hours if necessary. The magnesia method is advantageous in cases where the use of alkali causes decomposition and the production of colored substances which render titration uncertain.

(*e*) If hydrochloric acid (sulphuric acid) is without action on the hydroxyl compound, the acetyl derivative is heated with a known quantity of N/1 acid in a sealed tube or pressure-flask at 120°–150°, and the liberated acetic acid titrated.'

(*f*) Hydrolysis by means of sulphuric acid is especially advantageous when the original substance is insoluble in it. The acid employed should be free from oxides of nitrogen and contain 75 parts of concentrated acid in 32 parts of water. The dilute acid (10 cc) is mixed in a flask with a weighed quantity of the acetyl derivative (about 1 gram), which, if necessary, may be previously moistened with three or four drops of alcohol; the mixture is warmed on a hot but not boiling water-bath during a half hour, diluted with

¹ Schützenberger, Ann. de Ch. Ph. 84, 74. Herzfeld, B. 13, 266. Schmoeger, *Ibid.* 25, 1453.

eight volumes of water, then boiled during 3–4 hours on the water-bath, and allowed to remain during twenty-four hours at the ordinary temperature. The precipitated hydroxyl derivative is then collected on a filter.[1,2] Should the hydroxyl derivative not be completely insoluble in the dilute acid a blank experiment must be made and the correction introduced.[2]

(*g*) Hydriodic acid has also been employed for the hydrolysis of acetyl derivatives.[3]

(B) Additive Method.[4]

This may be regarded as complementary to the method described under *f*. In cases where the acetyl derivative is insoluble in cold water, and the acetylation proceeds quantitatively, the yield of product from a given weight of hydroxyl compound gives a measure of the number of acetyl groups introduced. This method has recently been applied to the investigation of the acetylation products of tannic acid.[5]

(C) Weighing the Potassium Acetate.[6]

This is applicable to compounds yielding potassium salts insoluble in absolute alcohol. The acetyl derivative (1–2 grams) is boiled with a slight excess of potassium hydroxide solution until it is com-

[1] Liebermann, B. **17**, 1682.   Herzig, M. **6**, 867–890.
[2] Ciamician and Silber, B. **28**, 1395.

[4] Goldschmiedt and Hemmelmayr, M. **15**, 321.
[5] H. Schiff, Ch. Ztg. **20**, 865.   [6] Wislicenus, Ann. **129**, 175.

pletely hydrolysed, water being added to replace that
evaporated.   The remaining alkali is neutralized with
carbonic anhydride, the liquid evaporated as com-
pletely as possible on the water-bath, and the residue
thoroughly extracted with absolute alcohol.   The
alcoholic solution is evaporated to dryness and the
residue again extracted, any insoluble matter being re-
moved and well washed, and the liquid evaporated in
a tared vessel.   The dried potassium acetate remain-
ing is then cautiously fused, allowed to cool over sul-
phuric acid, and weighed.

(D) Distillation Method.

Fresenius[1] first suggested that the acetic acid
from acetates could be liberated with phosphoric acid
and determined by distillation, with or without the
help of steam.   The method was then applied by
various chemists to the hydrolysis of acetyl deriva-
tives, but since they replaced the phosphoric acid by
sulphuric acid their results were not satisfactory.[2]
Subsequently the use of phosphoric acid was again
proposed.[3]   The acetyl product is hydrolysed by
means of alkalis or barium hydroxide, acidified at the
ordinary temperature with phosphoric acid, filtered,
and well washed; the filtrate and washings are then
distilled until the distillate is completely free from
acid, fresh water being introduced into the retort from

[1] Z. anal. Ch. 5, 315; 14, 172.
[2] Erdmann and Schulze, Ann. 216, 232.   Buchka and Erk,
18, 1142.   Schall, Ibid. 22, 1561.
[3] Herzig, M. 5, 90.

time to time as may be necessary. The distillation is
at first carried out over a flame and subsequently from
an oil-bath, the temperature being allowed to rise to
140°–150°, or a water-bath may be employed, in which
case the pressure is reduced.[1]   The connections must
all be of caoutchouc, as corks would absorb acetic acid,
and the alkali and acid employed must be free from
nitrates or nitrites.   The presence of chlorides is not
hurtful, as these do not liberate hydrogen chloride in
presence of the phosphoric acid, which is one advan-
tage it possesses over sulphuric acid.[2]   The distillate
is treated with baryta water in excess, and concen-
trated in a platinum dish, the excess of barium re-
moved by means of carbonic anhydride, and the fil-
trate evaporated to dryness; water is then added, the
liquid filtered, the insoluble portion well washed, and
the barium in the filtrate and washings determined as
sulphate, 1 gram $BaSO_4 = 0.5064$ gram $C_2H_3O_2$ or
0.5070 gram $C_2H_4O_2$.

The acetyl groups in acetylated gallic acids[3] were
determined by mixing the substance (3–4 grams) with
pure alcohol (5 cc) and sodium hydroxide (2–3 grams)
dissolved in water (15 cc).   After the hydrolysis was
completed, the alcohol was dissipated, the residue
acidified with phosphoric acid, the acetic acid driven
over in a current of steam, and its amount determined
by titrating the distillate with sodium hydrate solu-
tion, phenolphthaleïn being used as indicator.   One
source of error in this method arises from carbonic

[1] H. A. Michael, B. **27**, 2686.

[2] R. and H. Meyer, *Ibid.* **28**, 2967.

[3] P. Sisley, Bull. Soc. Chim. III. **11**, 562. Z. anal. Ch. **34**, 466.

anhydride, which is always present in the sodium hydrate, and is often produced by the hydrolysis itself; it naturally volatilizes together with the acetic acid. The difficulty may be avoided by heating the neutralized liquid to boiling, adding a very small quantity of $N/1$ acid, again boiling, and then neutralizing, the process being repeated until the neutralized liquid ceases to become red on boiling; this shows that all the carbonates are decomposed and no loss of acetic acid need be apprehended. It has been suggested[1] that, after the hydrolysis, elimination of the alcohol, and acidification by means of phosphoric acid, the liquid should be boiled in a reflux apparatus until the carbonic anhydride is removed, the subsequent operations being similar to those above described. Sources of error in this method are described on p. 26.[2]

BENZOYL DERIVATIVES.

(1) PREPARATION OF BENZOYL DERIVATIVES.

The following reagents are employed for the introduction of the benzoyl radicle into hydroxyl compounds:

Benzoyl chloride;
Benzoic anhydride, sodium benzoate;
p-Brombenzoyl chloride, p-Brombenzoic anhydride;
o-Brombenzoyl chloride;
m-Nitrobenzoyl chloride;
Phenylsulphonic chloride.

[2] Cf. Goldschmiedt and Hemmelmayr, M. **14**, 214; **15**, 319.

(A) Preparation of Benzoyl Derivatives by Means of Benzoyl Chloride.

(*a*) The "acid" method consists in heating the substance with the chloride at 180° during several hours in a reflux apparatus; it is not advisable to employ a sealed tube unless there is assurance that the hydrochloric acid will not cause secondary reactions nor, in the case of nitrogenous compounds, combine with them to form hydrochlorides which would then cease to react;[1] when this may occur the calculated quantity of chloride is employed, and the heating continued during about four hours at 100°–110°.

(*b*) The preceding method has been largely superseded by the use of the chloride in dilute aqueous alkaline solution.[2] It has been widely applied,[3] is usually known as the Schotten-Baumann method, and seldom fails to give good results. The substance is well shaken with sodium hydroxide solution (10%) and benzoyl chloride in excess until the smell of the latter is no longer noticeable.[4] If the benzoylation is to be as complete as possible more concentrated alkali should be used, say fifty parts of soda (20%) and six parts of the chloride in a closed flask.[5] The temperature should not exceed 25°,[6] and it is frequently desirable to add the alkali and chloride alternately little by little, whilst in some cases the former must be highly

[3] Baumann, B. **19**, 3218.   [4] Baumann.

[5] Panormow, B. **24**, R. 971.   [6] v. Pechmann, *Ibid.* **25**, 1045.

dilute.' It has also been found to be advisable to use the reagents in the proportion of seven molecules of soda and five of the chloride to each hydroxyl;[2] the alkali is dissolved in water (8–10 parts), and the shaking and gentle cooling continued during 10–15 minutes. For experiments with pyragallol the flask must be filled with coal-gas; in the case of similar substances which are so unstable in presence of caustic alkali, sodium carbonate,[x] bicarbonate, or sodium acetate may be used.[4] The precipitated benzoyl derivatives are usually white and semi-solid, and gradually harden and crystallize by prolonged contact with water; often traces of benzoyl chloride or benzoic acid are retained with great tenacity. For the purification of the benzoyl derivative of dextrose[6] it was necessary to dissolve out the crude product with ether; this was distilled off, and the residue treated with alcohol, which decomposed the last portions of benzoyl chloride that had not been removed by prolonged shaking of the ethereal solution with concentrated alkali. The alcoholic liquid was treated with soda in excess, precipitated with water, and the alcohol and ethylic benzoate removed by means of steam. The residue was then repeatedly recrystallized; at first from alcohol, then from glacial acetic acid. The pure compound is insoluble in ether, whilst the crude preparation readily dissolves. Benzoic acid may be frequently removed by sublimation in vacuo, or by extraction with boiling

[5] Skraup, M. **10**, 395.

carbon bisulphide.' Repeated extraction with alkali
is usually effective for the purification of benzoyl deriv-
atives soluble in ether, but it may produce partial hy-
drolysis. Commercial benzoyl chloride often contains
chlorobenzoyl chloride,² and since the chlorobenzoyl
derivatives are less soluble than the benzoyl derivatives
themselves, recrystallization is not adequate to secure a
product free from chlorine. It appears also that pure
benzoyl chloride may yield chloro-derivatives.³ Ben-
zotrichloride may contain benzal chloride; during the
conversion of the former into benzoyl chloride by the
action of lead oxide or zinc oxide the latter may yield
benzaldehyde, the presence of which would cause com-
plications.⁴ Lactones often yield benzoyl derivatives
of acids which are soluble in alkali; they are separated
by acidifying and removing the benzoic acid from the
precipitate by steam distillation.⁵

Schotten-Baumann's method has also been applied
to the preparation of acetyl derivatives, but with
comparatively little success on account of the greater
instability of acetyl chloride.⁶

(c) Benzoyl derivatives may also be prepared in
ethereal or benzene solution, with the help of dry
alkali carbonate,⁶ or of tertiary bases such as quinoline,
pyridine, or dimethyl aniline.⁷ (Cf. p. 6.)

(d) Sodium ethoxide⁸ may also be employed for the
decomposition of benzoyl chloride, and it was only in

⁷ L. Claisen, *Ibid.* 31, 1023.   ⁸ L. Claisen.

this manner that the benzoyl derivative of diacetyl-acetone could be obtained.' The ketone was heated in a reflux apparatus during six hours, with two molecular proportions each of benzoyl chloride and sodium ethoxide, which had been dried at 200°; after cooling, the sodium chloride and benzene were removed, the residue dissolved in ether, and the solution shaken with dilute alkali.

(c) Pyridine may be used in place of aqueous, or alcoholic alkali.² The product is triturated with dilute hydrochloric acid and recrystallized from alcohol.

(B) Preparation of Benzoyl Derivatives from Benzoic Anhydride.

(a) The hydroxyl compound is heated with benzoic anhydride, in an open vessel, at 150° during 1–2 hours.³

(b) In some cases the use of benzoic anhydride and sodium benzoate produces a more complete acylation than Schotten-Baumann's method.⁴ As an example of its use, scoparin (2 grams), benzoic anhydride (10 grams), and dry sodium benzoate (1 gram) were heated in an oil-bath at 190° during six hours; the product was treated at the ordinary temperature overnight with aqueous sodium hydroxide (2%), and the precipitated hexabenzoyl derivative purified by means of alcohol.

³ Liebermann, Ann. 169, 237.

⁴ Goldschmiedt and Hemmelmayr, M. 16, 327.

Not infrequently the addition of sodium benzoate is quite unnecessary.[1]

(C) Preparation of Substituted Benzoic Acid Derivatives and of Phenylsulphonic Chloride.

(*a*) *Parabromobenzoyl chloride.*[2] — Parabromobenzoic acid is intimately mixed with the equivalent quantity of phosphorus pentachloride, and warmed until the evolution of hydrogen chloride slackens. The product is then fractionated under reduced pressure; the pure compound melts at 42°, boils at 174° (102 mm), and is readily soluble in benzene and light petroleum.

(*b*) *Parabromobenzoic anhydride*[3] is prepared by heating sodium parabromobenzoate (3 parts) with parabromobenzoyl chloride (2 parts) at 200° during an hour. It melts at 212°, is almost insoluble in ether, carbon bisulphide, and glacial acetic acid, dissolves slightly in benzene, and is purified by recrystallization from chloroform.

(*c*) *Orthobromobenzoyl chloride*[4] is prepared in a similar manner to its isomer. It is a liquid, boiling at 241°–243°, and may be distilled under the ordinary pressure without decomposition.

(*d*) *Metanitrobenzoyl chloride*[5] is formed from the nitrobenzoic acid by gradually and intimately mixing with it the requisite amount of phosphorus penta-

[4] B. **21**, 2244.   Schöpf, *Ibid.* **23**, 3436.

[5] Claisen and Thompson, *Ibid.* **12**, 1943.

chloride; the phosphorus oxychloride is removed by distillation, and the residue fractionated under reduced pressure. It melts at 34° and boils at 183°–184° (50–55 mm).

(*e*) *Phenylsulphonic chloride*[1] is obtained by heating sodium phenylsulphonate with phosphorus pentachloride in equivalent proportions; when the action ceases the product is poured into water, the oily portion removed, washed with water, dissolved in ether, and the solution decolorized by treatment with animal charcoal. The compound melts at 14° and boils at 120° (10 mm).

(D) Acylation by Means of Substituted Benzoic Acid Derivatives and of Phenylsulphonic Chlorides.

(*a*) *Parabromobenzoyl chloride, or parabromobenzoic anyhdride,* has been used for acylation, the number of the original hydroxyl groups, being determined from the bromine content of the product.[2]

(*b*) *Orthobromobenzoyl chloride*[3] and *metanitrobenzoyl chloride*[4] are also well adapted for the determination of hydroxyl groups.

(*c*) *Phenylsulphonic chloride*[5] has been employed for

[1] Otto, Z. f. Ch. *1866*, 106.

the same purpose; it is either allowed to act like the benzoyl chloride in the Schotten-Baumann method, or it is warmed with the hydroxyl compound (phenol) and zinc dust, or zinc chloride.[1]

Phenylsulphonic derivatives are often more stable than the corresponding benzoyl compounds.[2]

(2) ANALYSIS OF BENZOYL DERIVATIVES.

(*a*) The exact number of benzoyl groups in many benzoyl derivatives is shown by their elementary analysis; in substitution products the amount of haloid, nitrogen, or sulphur is determined.

(*b*) The following method has been suggested for the direct determination of the benzoic acid:[3] The substance (about 0.5 gram) is hydrolysed by heating it during two hours at 100°, in a sealed tube, with concentrated hydrochloric acid (10 parts), which has been saturated with benzoic acid at the ordinary temperature. The product is allowed to remain 1–2 days at the ordinary temperature, filtered by means of the pump, and the precipitate washed, at first with more of the hydrochloric acid, then with a saturated aqueous solution of benzoic acid. The purified benzoic acid is now dissolved in $N/10$ sodium hydroxide solution in excess, titrated with excess of acid, and the neutralization effected with the needful quantity of the soda solution. The latter is standardized against pure benzoic acid,

---

[1] C. Schiaparelli, Gazz. **11**, 65.   [2] B. **30**, 669.
[3] G. Pum, M. **12**, 438.

phenolphthalein being employed as the indicator. The admixture of the acid and water during the washing of the benzoic acid always causes a precipitation of benzoic acid, so that the results obtained by this method are invariably about 1 per cent. too high; therefore, this amount must be deducted from the percentage of acid found, or the exact correction ascertained by means of a blank experiment with the same quantities of liquids as have been used in the main one.

(c) A method of more general application consists in separating the benzoic acid from the hydrolysed substance by means of a current of steam, and titrating the distillate;[1] its principle is therefore identical with the determination of acetyl groups, and it presupposes that the compound under examination is completely hydrolysed by alkalis, and yields no acid other than benzoic, volatile with steam. The substance (about 0.5 gram) is mixed with alcohol (30–50 cc) and potassium hydroxide in excess, and heated in a reflex apparatus; when the hydroylsis is completed the product is cooled, acidified with concentrated phosphoric acid solution or vitreous phosphoric acid, and distilled in a current of steam. The distillation is conducted slowly at first, and alcohol added, if necessary, by means of a dropping funnel, the object being to secure the gradual deposition, in a crystalline state, of the hydrolysis products as otherwise resinous substances might surround the benzoic acid and considerably

---

[1] R. and H. Meyer, B. 28, 2965.

hinder its volatilization.   When the distillate measures 1–1.5 liters, the following 150 cc are collected separately and tested for benzoic acid by titration, and, as soon as it is no longer present, the distillation is stopped.   The combined distillate is rendered alkaline with a known quantity of N/10 sodium hydrate solution, standardized against pure benzoic acid, and evaporated in a platinum, silver, or nickel dish to a volume of 100–150 cc, when the excess of alkali is titrated back, the liquid being boiled to expel carbonic anhydride; this may be regarded as accomplished when boiling during ten minutes produces no change in the indicator, which is aurin or rosolic acid.   In order to guard against the production of sulphites and sulphates, the concentration of the alkaline liquid is carried out by means of a spirit or petroleum lamp, unless a special gas burner is available.

(d) Benzoylmorphine has been examined by direct titration.[1]   The substance was dissolved in methylic alcohol, mixed with a little water, normal sodium hydrate solution (100 cc) added, and boiled in a reflux apparatus until a portion of it gave no turbidity with water; titration with normal hydrochloric acid, in presence of phenolphthaleïn, showed that the original compound was the monobenzoyl derivative. The same method was successfully applied to the analysis of dibenzoylpseudomorphine and tribenzoylmeythlpseudomorphine.

ACYLATION BY MEANS OF OTHER ACID RADICLES.

Propionic anhydride, isobutyric anhydride, opianic acid,[1] stearic anhydride,[2] and phenylacetyl chloride are sometimes used for acylation, as their relatively high boiling points facilitate their reaction with the hydroxyl compound.

(a) *Propionyl* derivatives are prepared by heating the substance with propionic anhydride, in a stout, closed bottle, at 100° during two hours; an open vessel may also be employed, and the reaction started by the addition of a drop of concentrated sulphuric acid.[3]

(b) *Isobutyryl* derivatives are prepared in a similar manner. Isobutyryl ostruthin was prepared by heating ostruthin (3 grams) with isobutyric anhydride (10 grams) in a sealed tube at 150° during 3 hours. The product was poured into water, allowed to remain until it became crystalline, washed with warm water until neutral, pressed, dried by means of filter paper, and recrystallized from alcohol.[4]

(c) *Phenylacetyl chloride* is not difficult to prepare,[5] and is used[6] like benzoyl chloride in Schotten-Baumann's method, the substance being dissolved in dilute aqueous potassium hydroxide solution, and well shaken with excess of the chloride.

(d) The extent to which *phosphoric acid* may prove useful remains at present undetermined.[7]

II. ALKYLATION OF HYDROXYL GROUPS,

The hydroxyl of phenol and primary alcohols is capable of alkylation, and the number of alkyl groups introduced may be determined from the resulting ethers by Zeisel's method (cf. p. 33). As a rule, the phenolic ethers are not hydrolysed by alkalies (cf. p. 457), hence it is possible to differentiate between the hydroxyl and carboxyl of the hydroxy acids. It has, however, been shown that the use of potassium hydroxide and alkyl iodides may lead to the production of compounds with the alkyl directly linked to carbon,[2] and that, on the other hand, hydroxyl in the ortho-position relative to carbonyl oxygen is determinable by acylation, but not by alkylation.[3]

Diazomethane may also be used as an alkylating agent.[4]

PREPARATION OF BENZYL DERIVATIVES,

Benzyl ethers of phenols are prepared by heating the latter in a reflux apparatus, during several hours, with the calculated quantities of sodium ethoxide and benzyl chloride in alcoholic solution, the precipitated sodium chloride is removed by filtration from the hot liquid,[5] and the composition of the

er determined by elementary analysis.   Benzyl
ide may also be employed for the preparation
these compounds.'

PREPARATION OF CARBAMATES BY MEANS OF CARBAMYL CHLORIDE.

PREPARATION OF CARBAMYL CHLORIDE.[2]

Ammonium chloride is placed in a distillation flask
ached to a long and wide condenser, heated at
out 400° in an air bath, and treated with a cur-
it of carbonyl chloride, dried by means of sul-
uric acid. The carbamyl chloride, which has a
ghly offensive smell, distils over and condenses to
colorless liquid, or to long, broad needles melting
50°.   It volatilizes at 61°–62°, and, after prolonged
inding, polymerizes to cyamelide, for which reason
should be employed as quickly as possible after its
eparation.   In contact with water or moist air, it
hydrolysed to carbonic anhydride and ammonium
loride.

PREPARATION OF CARBAMATES.

Carbamyl chloride reacts with hydroxyl derivatives
accordance with the equation:

$$NH_2CO.Cl + HO.R \longrightarrow NH_2.CO.OR + HCl,$$
ie resulting carbamates readily crystallize.[3]   It is

---

[1] M. & J. II., p. 125.

[2] Gattermann & G. Schmidt, B. **20**, 858.

[3] Gattermann, Ann. **244**, 38.

usually only necessary to mix the substances in equivalent proportion in ethereal solution as the reaction generally proceeds quantitatively at the ordinary temperature; in the case of some polybasic phenols gentle warming is requisite. The amount of nitrogen in the product is a measure of the number of hydoxyl groups in the original compound. Great excess of the chloride should not be used, as it may lead to the production of ethereal allophanates, $NH_2.CO.NH.CO.OR$.

IV. PREPARATION OF DIPHENYLCAR-BAMYL CHLORIDE $(C_6H_5)_2 N.CO Cl$.

This substance has been found especially useful in the investigation of rhodinol (geraniol).[1] It is prepared by dissolving diphenylamine (250 grams) in chloroform (700 cc), adding anhydrous pyridine (120 cc), and passing a current of carbonyl chloride (147 grams) into the liquid, which is maintained at 0°. After remaining during 5–6 hours, the chloroform is distilled off on the water-bath, and the residue crystallized from alcohol (1.5 liters). The yield is 300 grams, the product, after recrystallization from alcohol (1 liter), is pure, and melts at 84°.[2]

[1] Erdmann and Huth, J. pr. **53**, 45.

[2] *Ibid.* **56**, 7

V. PREPARATION OF PHENYLCARBAMIC ACID DERIVATIVES.

PREPARATION OF PHENYLISOCYANATE.[1]

Commercial phenylurethane (15 grams) is mixed with phosphoric anhydride (30 grams) in a small retort, and heated by means of a luminous flame, a large distillation flask being employed as receiver; the combined distillate from a number of such preparations is then fractionated once. The isocyanate boils at 169° (769 mm),[2] and the yield is 52–53 per cent.[3]

ACTION OF PHENYLISOCYANATE ON HYDROXYL DERIVATIVES.[4]

Ethereal phenylcarbamates are formed by the interaction of hydroxyl compounds and phenylisocyanate in equimolecular proportion in accordance with the equation :

$$R.HO + C_6H_5 N : CO \rightarrow C_6H_5NH.CO.OR.$$
The reaction often proceeds at the ordinary temperature, but it is best to rapidly boil the compounds, mixed in the requisite proportion, by means of a previously heated sand-bath, and complete the reaction by shaking and gentle warmth.[5] Polybasic phenols are

[1] H. Goldschmiedt, B. **25**, 2578, foot-note.
[2] Hofmann, B. **18**, 764.   [3] Zanoli, *Ibid.* **25**, 2578, foot-note.

[5] Tessmer, *Ibid.* **18**, 969.

heated in a sealed tube during 10–16 hours;' if the
compound eliminates water at this temperature the
phenylisocyanate is converted by it into carbonic an-
hydride and carbanilide.[2]   The duration of the boil-
ing in an open vessel should be shortened as much
as possible to reduce the production of diphenylcar-
bamide.   When cold the product of the reaction
is treated with a little benzene or ether to dissolve un-
altered phenylisocyanate, then, after the removal of
the benzene or ether, washed with cold water and
recrystallized from alcohol, ethylic acetate, or a
mixture of ether and light petroleum, which leaves
the sparingly soluble diphenylcarbamide undissolved.
The presence of negative groups in the molecule of
the hydroxyl derivative hinders or completely pre-
vents the reaction; thus trinitrophenol gives no deriv-
ative when heated at 180° under pressure.[3]

An attempt has been made to determine the
presence of hydroxyl groups by the use of 1 : 2 : 4-
chlordinitrobenzene.[4]

DETERMINATION OF METHOXYL, $CH_3\overset{1}{O}$-, ETHOXYL, $C_2H_5\overset{1}{O}$-, AND CARBOXYL, $\overset{1}{C}O.OH$.

I. DETERMINATION OF METHOXYL, $CH_3\overset{1}{O}$-.

S. ZEISEL'S METHOD.[1]

This method, which is distinguished for beauty and reliability, depends on the conversion of the methyl of the methoxy group into methyl iodide by means of hydriodic acid, the methyl iodide being then decomposed by alcoholic silver nitrate solution into silver iodide. The original apparatus, represented in Fig. 1, consists of a reversed condenser K, through which water at 40°–50° flows; at the lower end a flask A of 30–35 cc capacity is attached by means of a cork; the flask has a side tube sealed on through which a current of carbonic anhydride may be passed. A Geissler's potash bulb is connected to the upper end of the condenser, also by means of a cork; it contains 0.25–0.5 gram red phosphorus suspended in water, and is maintained at a temperature of 50°–60° by the water-bath in which it is placed. Its object is to absorb any iodine or hydriodic acid which might be carried over by the

---

methyl iodide vapor. The two flasks which complete
the apparatus have a capacity of 80 cc each, the first

FIG. 1.

contains 50 cc of alcoholic silver nitrate solution,
the second 25 cc; they are connected by means of

corks, and may be conveniently replaced by two distillation flasks, the side tube of the first being bent downwards at a right angle into the second. A modified apparatus has been described, which serves as a combined condenser and washing arrangement,[1] and also a second one, which has in addition a very convenient appliance for heating and supplying the water to the condenser.[2] Modified boiling flasks,[3] (Fig. 2), which prevent the action of the heated hydriodic acid on the cork, have been designed. If the substance under examination is not volatile, the condenser may be replaced by a vertical tube bent back in a U shape. The method is not applicable to compounds containing sulphur, and the hydriodic acid employed must not have been prepared by means of hydrogen sulphide, otherwise it is difficult to completely free it from volatile sulphur compounds, the presence of which would be apt to cause the formation of mercaptanes and silver sulphide. C. A. F. Kahlbaum, of Berlin, supplies "hydriodic acid for methoxyl determination," which is prepared by means of phosphorus, and is trustworthy. Should a blank experiment show that the hydriodic acid produces a perceptible precipitate in the silver nitrate solution, it must be purified by distillation, the first and last quarters of the distillate being rejected; it should have a sp. gr. $= 1.68 – 1.72$. Boiling the acid with a reversed condenser, even

FIG. 2.

---

[1] Benedikt and Grüssner, Ch. Ztg. **13**, 872.

[2] L. Ehmann, *Ibid.* **14**. 1767; **15**, 221.

[3] Benedikt, *Ibid.* **13**, 872. M. Bamberger, M. **15**, 505.

during several days,[1] does not suffice for its purification. The *silver nitrate* solution is prepared by dissolving the fused salt (2 parts) in water (5 parts) and adding absolute alcohol (45 parts); it is kept in the dark, and the quantity required for each determination filtered into the absorption flasks.

I. METHOD FOR NON-VOLATILE SUBSTANCES.

After the apparatus is put together, tested, and found to be air-tight, the silver nitrate solution is introduced into the absorption flasks, and the substance (0.2–0.3 gram), together with the hydriodic acid (10 cc), placed in the distillation flask; unless Bamberger's pattern is employed this should also contain a few pieces of porous plate to regulate the ebullition; it is then heated to boiling in a glycerine-bath. During this time the current of carbonic anhydride is passed through the apparatus at the rate of three bubbles in two seconds. The gas employed must be washed with water, and also with silver nitrate solution, to remove any hydrogen sulphide arising from impurities in the marble. The warm water must also be supplied to the condenser and the bath containing the potash bulbs. Some 10–15 minutes after the acid begins to boil the silver nitrate becomes turbid and soon a white double compound of silver nitrate and silver iodide precipitates in the first flask; the liquid in the second one usually remains clear, but sometimes becomes opalescent if the current of carbonic anhydride is very rapid or the substance

---

[1] Benedikt.

particularly rich in methoxyl groups, these conditions may also cause the precipitate to become yellow. The conclusion of the experiment is readily indicated by the complete subsidence of the precipitate, which becomes crystalline; the time required is 1–2 hours. The tubes and flasks with the silver solution are disconnected, and the second one diluted with five parts of water; if no precipitate appears after remaining several minutes nothing more is done to it, otherwise it is added to the contents of the first flask, which are poured into a beaker, any precipitate adhering to the tubes is removed to the beaker by means of a feather and jet of water; the volume is now made up to about 500 cc with water, evaporated to one half on the water-bath, then water and a drop of nitric acid added, and the liquid digested until the silver iodide is completely precipitated; it is then filtered and weighed in the usual manner. The precipitate adhering to the tubes is usually dark-colored, possibly from the presence of a trace of phosphorus, but this does not affect the accuracy of the determination. 100 parts of silver iodide = 13.20 parts of CH_3O = 6.38 parts of CH_3. The method is applicable to compounds containing chlorine, bromine,[1] or nitro-groups, but not to sulphur compounds.[2] In the case of nitro-derivatives, or other compounds which readily liberate iodine from hydriodic acid, it is desirable to place a little red phosphorus in the boiling-flask. The potash bulbs require refilling after four or five determinations. Hydriodic acid causes many sub-

[1] G. Pum, M. **14**, 498.

[2] Zeisel. *Ibid.* **7**, 409.   Benedikt and Bamberger, *Ibid.* **12**, 1.

stances to become resinous, and the resin may protect
a portion of the methoxy compound from the action of
the acid.   This difficulty may be overcome by adding
to the acid acetic anhydride (6–8 volumes per cent), as
was shown in the case of methyl and acetylethyl-
quercetin, rhamnetin, and triethoxyphloroglucinol.'
The method is also well adapted for the determination
of alcohol of crystallization.[2]

2. MODIFICATIONS OF THE METHOD FOR ITS USE WITH VOLATILE COMPOUNDS.

Volatile substances may usually be treated in the
manner described above if, at the commencement of
the experiment, a slow stream of carbonic anhydride is
employed and cold water run through the condenser.
The following special modifications for particularly
volatile compounds have been suggested.[3]   The sub-
stance (0.1–0.3 gram) is sealed into a small bulb of
thin glass, which is sealed up in a larger tube together
with hydriodic acid (10 cc, sp. gr. = 1.7) and a
piece of heavy glass about 2 cm in length with a
sharp corner.   The heavy glass is to assist in break-
ing the bulb with the substance before the heating,
but is unnecessary if the latter is enclosed in test-
tube glass with a long capillary.   The larger tube
is 30–35 cm long and 1.2–1.5 cm inner diameter;
both ends are drawn out, the one to fit into a tube
10 cm long and 1–2 cm inner diameter, which is

[1] Herzig. M. 9, 544.   Cf. Pomeranz, *Ibid.* 12, 383.

[2] J. Herzig and H. Meyer, *Ibid.* 17, 437.

[3] Zeisel, *Ibid.* 7, 406.

sealed to a wider tube, the other so that a piece of stout rubber tube will fit over it quite tightly. The drawn-out ends must be strong enough to resist the pressure during the heating, and sufficiently thin to be readily broken after being scratched with a file. The substance and hydriodic acid are heated at 130° during two hours, then, when cold, one point of the tube is fitted into the narrow one mentioned above, the wide portion of which passes through a triply bored cork into a wide-mouthed flask. Into the second opening of the cork the condenser fits, whilst the third contains a piece of stout glass rod bent to a Z form; by turning this the drawn-out end of the heating-tube is broken. The contents are transferred to the flask partly by shaking, partly by gently warming; the upper capillary is covered with a piece of rubber, the end broken, and a current of carbonic anhydride immediately passed through the apparatus. The determination then proceeds in the manner already described.

3. MODIFICATION OF ZEISEL'S METHOD.[1]

Instead of red phosphorus and water the potash bulbs contain a solution consisting of arsenious anhydride (1 part), potassium carbonate (1 part), and water (10 parts). The bulbs must be refilled for each determination to prevent the apparatus becoming choked with precipitated anhydride, but this is compensated for by the fact that not the slightest reduction (black-

---

[1] J. Gregor, M. **19**, 116.

ening) of the silver nitrate solution takes place. The
N/10 *silver nitrate solution* is made by dissolving the
nitrate (17 grams) in water (30 cc) and diluting to a
liter with commercial absolute alcohol, its titer being
determined by means of N/10 potassium thiocyanate
solution. For the alkyloxyl determination the silver
solution (75 cc) is acidified with a few drops of nitric
acid, free from nitrous acid, and divided between the
two absorption flasks. At the conclusion of the ex-
periment the silver solution with the precipitate is di-
luted with water to 250 cc, cautiously shaken, filtered
by means of a dry ribbed filter into a dry flask, and
50 cc or 100 cc of the clear filtrate acidified with
nitric acid, free from nitrous acid, treated with ferric
sulphate solution, and titrated in the ordinary manner.[1]

METHOD FOR THE DIFFERENTIATION OF METHOXYL AND ETHOXYL.

Zeisel's method does not distinguish between meth-
oxyl and ethoxyl; should this be necessary, the alkyl
iodide must be prepared in quantity sufficient for its
identification, or, if possible, Lieben's iodoform test
must be applied. For the differentiation of the alkyls
the investigation of the action of phenyl isocyanate
on the alkyloxy derivatives has been suggested.[2]
The compound is heated with phenyl isocyanate, in
equimolecular proportion, at 150° during several
hours in a sealed tube. The product is steam-dis-
tilled and the volatile portion purified by recrystal-

[1] Volhard, J. pr. **9**, 217. Ann. **190**, 1. Z. anal. **13**, 171; **17**, 482.
[2] Beckmann, Ann. **292**, 9, 13.

lization from a mixture of ether and light petroleum; methylphenylurethane melts at 47°, ethylphenylurethane at 50°, and they can be further distinguished by analysis.

DETERMINATION OF ETHOXYL ($C_2H_5\overset{|}{O}-$).

The determination of ethoxyl [1] is carried out exactly in the manner described in the preceding section for methoxyl except that the water in the condenser and in the bath surrounding the potash bulbs should be heated at about 80°. 100 parts of silver iodide = 19.21 parts C_2H_6O = 12.34 parts C_2H_6.

DETERMINATION OF CARBOXYL ($C\overset{O}{\underset{|}{H}}.OH$).

The following methods are employed for the determination of the basicity of organic acids:

(A) Analysis of metallic salts of the acid.

(B) Titration.

(C) Etherification.

(D) Determination of the electrolytic conductivity of the sodium salts.

(E) Indirect methods:

      (1) Carbonate method.

      (2) Ammonia method.

      (3) Hydrogen sulphide method.

      (4) Iodine method.

It is easy to decide which of these methods is the most suitable for any special case, but the qualitative differentiation between carboxyl and phenolic hy-

[1] Zeisel, M, 7, 406.

droxyl frequently presents difficulties that can only be overcome with certainty by the preparation of the amide and its conversion into the nitrile.

(A) Determination of Carboxyl by Analysis of Metallic Salts of the Acid.

In many cases the number of carboxyl groups in an organic compound may be determined by the analysis of its neutral salts; of these the *silver salts* are usually the most appropriate, as they are generally formed directly without admixture of hydrogen salts and are almost always anhydrous. Exceptions to this rule are, however, encountered; thus the silver salts of cantharidinic acid,[1] camphoglycuronic acid,[2] and meta-quinaldinic acid[3] crystallize with one, three and four molecules of water respectively, and hydrogen silver salts,[4] though not of frequent occurrence, are known. Aromatic hydroxymonocarboxylic acids containing two nitro-groups often give salts containing two atoms of silver. As examples may be mentioned 3 : 5-dinitro-hydrocumaric, 1 : 3 : 5-dinitroparahydroxybenzoic and 2 : 6-dinitro-5-hydroxy-3-4-dimethylbenzoic acids.[5] Many silver salts are very sensitive to light or air, and some, like silver oxalate, are explosive; for the analysis of such the compound is dissolved or suspended in water or acid, and treated with hydrogen

[1] Homolka, B. **19**, 1083.

[2] Schmiedeberg and Meyer, Z. physiol. Chem. **3**, 433.

[3] Eckhardt, B. **22**, 276.

[4] A list of them is given in Lassar-Cohn " Manual of Organic Chemistry," translated by Alex. Smith, p. 345.

[5] W. H. Perkin, Jun., Journ. Chem. Soc. (*1899*), **75**, 176.

sulphide or hydrochloric acid. Silver salts which do not explode when heated are usually analyzed by ignition in a porcelain crucible; if the residual silver contains carbon it is dissolved in nitric acid, the solution diluted and filtered, and the silver precipitated by means of hydrochloric acid.

Pyridine and quinoline derivatives and amino-acids in particular often give characteristic *copper and nickel salts*, whilst, in the aliphatic series, the *zinc salts* may often be usefully employed. *Sodium, potassium, calcium, barium, magnesium*, and, less frequently, *lead salts* are also sometimes used for the determination of basicity, but, as many acids do not yield well-defined neutral salts, and groups other than carboxyl can exchange hydrogen for metal, the method has not a very wide application.

(B) Titration of Acids.

The basicity of a carboxyl derivative may often be determined by titration if the molecular weight of the compound is known; $N/10$ sodium hydroxide, potassium hydroxide, or barium hydroxide may be used for the titration in aqueous solution, or, in the case of the first two, in alcoholic solution. $N/2$ ammonium hydroxide has also been employed.[1] The acids used are generally hydrochloric or sulphuric, but the latter is unsuited for work with alcoholic solutions, as the precipitation of insoluble sulphates prevents a correct observation of the end reaction. The liquid, alcohol, ether, etc., in which the compound under examination

[1] Haidinger and Lieben, M. **6**, 292.

is dissolved must either be free from acids or must be previously accurately neutralized by means of N/10 alkali. Phenolphthaleïn, methyl orange, rosolic acid, curcumin, or litmus, are usually employed as indicators, the first two more frequently than the others. If the liquid is dark colored the use of "alkali blue" is often convenient, and attention must always be paid to the possible presence of carbonic anhydride. A somewhat curious and interesting attempt has been made to determine the neutrality by taste.[1]

(C) Etherification.

In very many cases carboxylic and phenolic hydrogen may be differentiated by the etherification of the compound with alcohol and hydrogen chloride. It has, however, been shown[2] that acids with the group

$$\overset{t'}{C}.COOH$$

(t and t' = tertiary carbon atom) do not

$$\overset{C}{t}\quad\overset{C}{t}$$
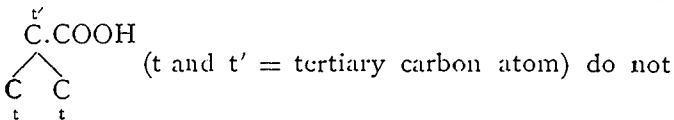

yield esters with alcohol and hydrogen chloride if both the carbon atoms marked t are linked to Cl, Br, I, or NO_2, whilst the groups of smaller mass F, CH_3, OH in the same positions greatly retard, but do not entirely prevent, etherification. On the other hand, certain phenols such as phloroglucinol,[3] which gives a diether, hydroxyanthracene (anthrol and α- and β-naphthol[4]) yield ethers when treated with hydrogen

[1] T. W. Richards, Am. Chem. Journ., **20**, 125.

[2] V. Meyer and others. Many papers appeared on the subject beginning B. **27**, 510, and ending **29**, 2569.

[3] *Ibid.* **17**, 2106 ; **21**, 603.

[4] Liebermann and Hagen, *Ibid.* **15**, 1,427.

chloride and alcohol.   The etherification is most conveniently carried out by boiling the substance during 3–5 hours in a reflux apparatus with a large excess of absolute alcohol containing 3–5 per cent of hydrogen chloride or sulphuric acid.[1]   Occasionally alcohol of 95 per cent may be employed if more sulphuric acid is used.[2]   Some substances form additive compounds with alcohol and hydrogen chloride.[3]   This, as also the contamination of the ester by traces of chlorine derivatives, which can only be removed with difficulty, may lead to confusion.

The esters obtained by acid or alkaline etherification are, in general, distinguished from the phenolic ethers by the ease with which aqueous or alcoholic alkalis hydrolyse them, but exceptions are known since trinitromethoxybenzene (methoxy picrate) when boiled with concentrated potassium hydroxide yields methyl alcohol and potassium picrate,[4] and methoxy-anthracene (methyl anthranol) is also decomposed by boiling with alcoholic potash.[5]   The composition of the esters is determined by elementary analysis, and the alkyloxy groups by the methods described in the earlier portion of this chapter.

(D). Determination of the Basicity of Acids by means of the Electrolytic Conductivity of the Sodium Salts.

It has been shown that the degree of electrolytic conductivity of the sodium salt is a certain indication of the basicity of the corresponding acid.[1] The method is of very general application, since insoluble acids usually yield sodium salts which dissolve in water, but it fails in the case of acids which are so feeble that their sodium salts are hydrolysed by water sufficiently to impart an alkaline reaction to the solution. The following apparatus is required for the determination :

(1) A small *induction coil* (J, Fig. 5), such as is employed for medicinal purposes, and which requires only one or two cells for prolonged use. The spring of the interrupter must vibrate rapidly so as to produce a high pitched sound in the telephone, as this is more easily heard than a deeper tone.

(2) A *bridge* consisting of a scale 100 cm in length divided into millimeters; along it stretches a wire provided with a sliding contact. The wire is of platinum, German silver, platinoid, or manganin, of which the last is the best on account of its low temperature coefficient. The wire must be calibrated.[2]

(3) A *rheostat* for adjusting the resistance (W, Fig. 5).

---

[1] Ostwald, Z. **2**, 901; **1**, 74. Walden, *Ibid.* **1**, 529; **2**, 49.

[2] Strouhal and Barus, Wied. Ann. **10**, 326. The method is also described by Jones. " Freezing-point, Boiling-point, and Conductivity Methods," Chem. Pub. Co., 1897.

(4) A *resistance cell* for the electrolyte (E, Fig. 5). Kohlrausch's form (Fig. 3) is used for low resistances whilst that of Arrhenius (Fig. 4) is employed for dilute solution where the resistance is high. The electrodes must be platinised by filling the vessel with a dilute solution of hydroplatinochloric acid

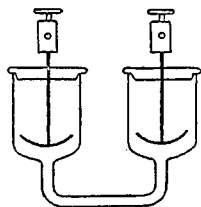

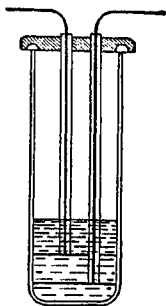

Fig. 3.

Fig. 4.

and passing a current of 4–5 volts. The direction of the current is changed occasionally and the electrolysis continued until both electrodes are completely covered with platinum black, which only requires a short time ; the platinum chloride in the cell is now replaced by sodium hydroxide solution, the electrolysis continued for a few moments, the electrodes then thoroughly and carefully washed with hydrochloric acid, and finally with water ; the sodium hydroxide removes all chlorine which is otherwise very obstinately retained by the platinum. The use of Lummer and Kurlbaum's solution for platinizing is highly recommended, as the tone minima are much more distinct.[1] The solution consists of platinum chloride (1 part), lead acetate (0.008 part), and water (30 parts) ; it is electrolysed with a current density of 0.03 ampères per sq. cm., the direction of the current being frequently changed and continued until each

[1] Kohlrausch, Wied. Ann. 1897, p. 315 ; E. Cohen, Z. **25**, 1611.

electrode has been the cathode during at least fifteen minutes.

(5) A *telephone*.   Ostwald states that the most sensitive ones are made by Ericsson of Stockholm, but for ordinary purposes a Bell instrument is sufficiently good.   In using it the unoccupied ear may be closed with cotton to exclude external sounds.

(6) A *water-bath* with *stirrer* and *thermometer*, or a *thermostat*.'

The apparatus is arranged in the form of Kirchhoff's modification of the Wheatstone bridge (Fig. 5), the connections being made with stout copper wire. The induction coil is enclosed in a sound tight case,

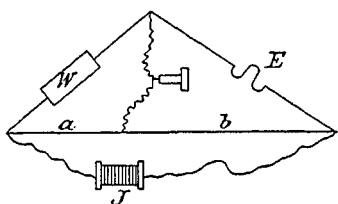

Fig 5.

or is placed in another room.   If determinations of solutions of a substance at different concentrations are to be made the solution is most conveniently prepared in the resistance cell itself, portions are then withdrawn by means of an accurately calibrated pipette, and the desired volume of water added which has previously been brought to the necessary temperature in the thermostat.   As a rule the telephone does not give an absolutely sharp minimum at any given point, but it is easy to find two limits beyond either of which the tone rises; these are usually separated by an interval of 0.5–2 mm, and the required position is taken as midway

---

¹ Ostwald, Z. **2,** 564, where also a good description of the other parts of the apparatus is given.

between them. A little experience enables the conductivity to be determined with an accuracy of 0.1 per cent. If the tone minimum becomes indistinct the electrodes must be replatinised. The conductivity is calculated from the measurements by means of the formula $\mu = k . \dfrac{v . a}{w . b}$, where

$\mu =$ the molecular conductivity;

$v =$ the volume of the solution in liters which contains a gram molecule of the electrolyte;

$w =$ the adjusting resistance;

$a =$ the length of wire to the left of the sliding contact (Fig. 5);

$b =$ that to the right of the contact (Fig. 5)

$k =$ the resistance of the cell.

The value of k is determined by measuring the conductivity of N/50 solution of potassium chloride, for which Kohlrausch found the values:

$$\mu = 112.2 \text{ at } 18°.$$
$$\mu = 129.7 \text{ at } 25°.$$

Other solutions may also be used.[1] The value $\dfrac{b}{a}$ for a wire 1000 mm in length has been calculated by Obach and an abbreviated table of the results is given in the appendix. The conductivity of the water employed, which should be as highly purified from dissolved substances as possible, is determined in the same manner as that of the solution, the value for

---

[1] Wiedemann and Ebert, Physik. Praktikum, p. 389.

each liter (v) is calculated according to the formula, and subtracted from the uncorrected value of μ. For basicity determinations the conductivity is usually determined at concentrations of one gram molecule in 32 and 1024 liters respectively. The mean difference $\varDelta$ between these values is as follows:

Monobasic acids.... $\varDelta = 10.4 = 1 \times 10.4$
Dibasic   "   .... $\varDelta = 19.0 = 2 \times 9.5$
Tribasic   "   .... $\varDelta = 30.2 = 3 \times 10.1$
Tetrabasic   "   .... $\varDelta = 41.1 = 4 \times 10.3$
Pentabasic   "   .... $\varDelta = 50.1 = 5 \times 10$

A method has been described[1] for determining the basicity of acids based on the alterations which they exhibit in electrolytic conductivity on the addition of alkali.

Instead of the telephone and induction coil, a double commutator and a galvanometer may be used to determine the electrolytic conductivity, the commutating apparatus, termed a secohmmeter, is so arranged that one commutator is included in the battery circuit and the other in that of the galvanometer; on rotating the current is reversed in the liquid so frequently that polarization is annulled whilst the galvanometer is commuted.[2]

D. Berthelot, C. r. **112**, 287.
Cahart and Patterson, " Electrical Measurements," p. 109.

(E) Indirect Methods for the Determination of the Basicity of Acids.

These methods may be divided into four classes according to the nature of the substance liberated by the acid :

(1) *Carbonate method.*
(2) *Ammonia method.*
(3) *Hydrogen sulphide method.*
(4) *Iodine-oxygen method.*

(1) *Carbonate Method.*—The substance (0.5–1 gram) is dissolved in water in a flask closed by a rubber stopper with three holes. In one hole a condensing tube is fitted, which, at the lower end, is flush with the stopper whilst the upper end is connected with an absorption apparatus consisting of two calcium chloride tubes and potash bulbs. Through the second hole a tube passes to the bottom of the flask, the end being drawn out and bent upwards; by means of this tube a current of air, free from carbonic anhydride, is passed. The third hole of the flask is closed with a small dropping funnel, the end of which is also drawn out and bent upwards and dips below the liquid in the flask. The solution of the acid is gently boiled, and barium carbonate, in the form of a thin paste, is added in small quantities by means of the funnel. When the operation is completed the apparatus is allowed to cool in a current of purified air, again boiled, cooled, and the absorption bulbs weighed.[1] A similar method,

---

[1] Goldschmiedt and Hemmelmayr, M. **14**, 210.

based on the decomposition of sodium hydrogen carbonate, has also been described.[1]

(2) *Ammonia Method.* The acid (about 1 gram) is dissolved in excess of alcoholic potassium hydroxide, and made up to 250 cc with alcohol of the same strength (93 per cent). The excess of alkali is neutralized by carbonic anhydride, the precipitated carbonate and bicarbonate filtered off and washed with 50 cc of alcohol (98 per cent). The alcohol is removed from the filtrate and washings by distillation, and the residue boiled with 100 cc of ammonium chloride solution (10 per cent). The potassium salt of the acid decomposes the ammonium chloride, and the liberated ammonia is determined in the usual manner. The amount of alkali carbonate dissolved by 100 cc of alcohol (93 per cent) is equivalent to 0.34 cc of normal acid; a correction for this must be applied and also one for the ammonium chloride hydrolised by the water; this is determined by a blank experiment, 100 cc of the solution being boiled during the same length of time, 1–2 hours, as in the actual determination.[2]

The method gives good results with the feebler fatty acids, and is especially useful when the dark color of the solution prevents direct titration.

(3) *Hydrogen Sulphide Method.*[3] Compounds containing carboxyl liberate hydrogen sulphide from certain metallo-hydrogen sulphides when allowed to react in
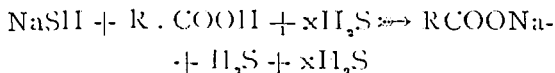

[1] Vohl B. **10**, 1807. C. Jehn, *Ibid.* **10**, 2108.

[2] P. C. McIlhiney, J. Am. **16**, 408.

[3] F. Fuchs, M. **9**, 1132, 1143; **11**, 363.

an atmosphere of hydrogen sulphide, according to the equation:

$$NaSH + R . COOH + xH_2S \Longrightarrow RCOONa + H_2S + xH_2S$$

two volumes of hydrogen sulphide being liberated for each volume of hydrogen, replaceable by metal, in the original compound. Hydroxyl hydrogen in phenols, alcohols, and hydroxy-acids does not react with the metallo-hydrogen sulphides.

Preparation of the Solution.

The majority of alkali salts are sparingly soluble in solutions of the hydrosulphides, hence the solution of the latter must not be so concentrated as to hinder the reaction from being rapidly completed. Potassium hydroxide solution, not exceeding 10 per cent, is boiled with baryta water in excess, the flask closed, and the liquid allowed to cool and deposit barium carbonate. The clear solution is now poured into the vessel to be used for the analysis, and saturated with hydrogen sulphide.

Method of Analysis.

The evolved hydrogen sulphide may be determined:

(*a*) *volumetrically;*

(*b*) *by titration.*

The former method is the easier and is therefore generally employed.

(*a*) *Volumetric Determination.*

This method is based on the same principle as Victor Meyer's vapor density determination. The apparatus, Fig. 6, consists of a long-necked flask *A*,

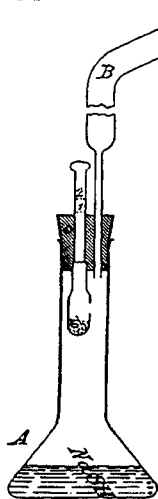

made of thick glass; it is fitted with a rubber stopper *c* through which the delivery tube *B* passes, this is wide at one end but terminates in a capillary at the other. The second hole of the stopper is closed by means of a glass rod from

Fig. 6.

which the vessel containing the substance is suspended. Previous to the determination the greater portion of the flask is filled with hydrogen sulphide, but the upper portion of the neck and the delivery tube contain air which is expelled by the evolved hydrogen sulphide and collected over water in a graduated tube. The substance under examination is dried, finely powdered, and about 0.5 gram weighed into the small vessel, the glass rod being pressed into the rubber stopper as far as the mark 1, the vessel fitted on to it by means of the stopper, which, with the delivery tube, is passed air-tight into the flask. The apparatus is allowed to remain for a few moments to equalize the

temperature, then the capillary end of the delivery-tube is dipped into water below the open end of the gas-measuring vessel, and the vessel with the substance dropped into the sulphide solution by pushing in the rod to the mark 2, care being taken not to alter the position of the stopper itself. The evolution of hydrogen sulphide ceases after a few minutes. The same solution may be employed for a second or third determination, but each time the delivery-tube must be previously filled with dry air. The weight of carboxyl hydrogen G is calculated from the results by the formula:

$$G = \frac{\frac{1}{2}V(b - W)}{760(1 + 0.00366t)} \cdot 0.0000896$$
$$= \frac{V.(b - w).0.00000005895}{1 + 0.00366t},$$

where $V =$ the observed volume of air displaced in cc, $b =$ the height of the barometer, and w the tension of aqueous vapor at the observed temperature t.

(b) *Titration Method.*

The apparatus employed consists of a short-necked flask A, Fig. 7, fitted with a rubber stopper and glass rod exactly as used in the preceding method, but the delivery-tube is short in order to expedite the expulsion of air. Before the stopper, with the substance adjusted in the manner described above, is inserted into the flask, tartaric

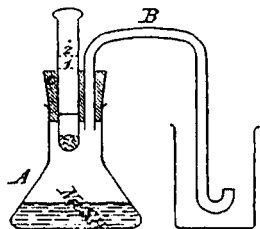

Fig. 7.

acid or oxalic acid (about 0.25 gram) is dropped into
the potassium hydrogen sulphide solution and the
stopper immediately inserted air-tight as shown.   As
soon as the solution of gas ceases the beaker repre-
sented in the figure is replaced by a smaller one contain-
ing concentrated potassium hydroxide solution.   Some
of this rises in the tube on account of the absorption
of the gas, but the error so introduced compensates
itself at the end of the experiment.   As soon as the
beaker of alkali has been put into position, the sub-
stance is dropped into the sulphide solution with the
same   precautions   as   observed   in   the   preceding
method; after the cession of the gas evolution, which
continues during 1–5 minutes, the pressure is adjusted
by lowering the beaker, the contents are poured into
a large flask, and the beaker and evolution tube
washed. The alkali and washings are diluted to about
500 cc, neutralized with acetic acid, and titrated with
iodine solution in presence of starch.   Since

$$H = H_2S = I_2,$$
the iodine required, divided by 2×126.5, gives the
weight of the replaceable hydrogen.   The error due
to the insertion of the glass rod from mark 1 to 2 may
be determined by means of a blank experiment, but it
is so small as to be usually negligible.   More recently
the action of substituted phenols, etc., on alkali hy-
drogen sulphides has been investigated[1] with the
following results:

(1) Haloïd substituted phenols with one hydroxyl

[1] Fuchs, M. 11, 363.

group are without action on the sulphides, but if *two* hydroxyl groups are present *one* reacts.

(2) Only the *paramononitro*-phenols react.

(3) Under certain conditions the presence of carboxyl groups causes the phenolic hydroxyl to decompose the sulphides.

(4) In general lactones do not react, but lactone-acids may suffer partial resolution.'

With the above exceptions the method provides a ready means of differentiating carboxylic hydrogen from phenolic or alcoholic, a distinction which the two preceding methods do not furnish with certainty.

(4) *Iodine-oxygen Method.*[2] This depends on the fact that even feeble organic acids liberate iodine from potassium iodide and potassium iodate in accordance with the equation:

$$6R.COOH + 5KI + KIO_3 \longrightarrow 6R.COOK + 3I_2 + 3H_2O.$$
The liberated diodine, in presence of alkali, evolves oxygen from hydrogen peroxide:

$$I_2 + 2KOH \longrightarrow KOI + KI + H_2O \text{ and}$$
$$KOI + H_2O_2 \longrightarrow KI + H_2O + O_2.$$
The oxygen may be measured in a modified Wagner & Knop's Azotometer,[3] or in any other convenient vessel.

The *apparatus* consists of an evolution flask, with a small cylinder of about 20 cc capacity fused to the middle of the bottom inside, and a large glass cylinder

[1] H. Meyer, M. **19**, 715.
[2] Baumann and Kux, Z. Anal. Ch. **32**, 129.   [3] *Ibid.* **13**, 389.

with two communicating burettes and a thermometer
fastened to the interior of the cover. The cylinder
and burettes are filled with water, the latter by con-
necting them with a flask from which water is forced
by air pressure from a hand blower, the connecting
tube being provided, if needful, with a stop-cock. The
evolution flask is closed by means of a rubber stopper
carrying a tube with a stop-cock which is connected
with the graduated burette below the stop-cock in
which the latter terminates, and which is used for ad-
justing the pressure. The temperature of the evolution
flask is equalized before and after the determination
by placing it in water of the same temperature as that
in the large cylinder enclosing the burettes. The
following *reagents* are required:

(1) Potassium iodide } Absolutely free from acid.
(2)   "   iodate }
(3) Hydrogen peroxide 2–3 per cent. solution.
(4) Aqueous potassium hydroxide solution (1 : 1).
(5) Distilled water, recently boiled and free from
     carbonic anhydride.

The *determination* is carried out in the following
manner: The acid (0.1–0.2 gram) is mixed with finely
divided potassium iodate (about 0.2 gram), potassium
iodide (2 grams), and water (40 cc) in a bottle provided
with a well-fitting stopper, and allowed to remain at
the ordinary temperature during twelve hours, or at
70°–80° during a half hour, until the iodine is com-
pletely precipitated. The solution is now transferred
to the outer portion of the evolution flask, the bottle
being washed with not more than 10 cc water. Into

the inner cylinder of the evolution flask is poured by means of a funnel a mixture consisting of hydrogen peroxide (2 cc) and potash solution (4 cc), made immediately before use and cooled to the ordinary temperature. The evolution flask is now closed with its stopper and allowed to stand in water during ten minutes, the stopcock of the burette being opened to equalize the pressure; at the end of this time it is closed, the level adjusted to the zero mark, and if after five minutes no change takes place the experiment is proceeded with, otherwise the cooling is continued during another five minutes. When equilibrium is established 30–40 cc of water are run from the burette in order to reduce the pressure, the evolution flask is removed from the cooling vessel by means of a cloth and rotated so that the liquids at first circulate without mixing and are then suddenly brought into contact. The shaking is continued vigorously for a short time and the flask then returned to the cooling vessel. The evolution of oxygen begins at once, and is completed in a few seconds; after about ten minutes the pressure in the two burettes is adjusted and the volume read the number of cc of gas, multiplied by the value in the table' in the appendix corresponding to the pressure and temperature, gives directly the weight of carboxylic hydrogen. An *iodometric method* for the determination of acids has also been described, for details the original paper should be consulted.[2]

CHAPTER III.

DETERMINATION OF CARBONYL ($\overset{\text{II}}{\text{C}}$O).

The presence of the carbonyl group in aldehydes ketones, etc., is recognized by the preparation of derivatives of the following compounds:

(1) Phenylhydrazine.
(2) Hydroxylamine.
(3) Semicarbazide.
(4) Amidoguanidine.
(5) Paramidodimethylaniline.

### (1) CARBONYL DETERMINATION BY MEANS OF PHENYLHYDRAZINE.

The method is divisible as follows:

(A) *Preparation of phenylhydrazones from phenylhydrazine.*
(B) *Preparation of substituted hydrazones.*
(C) *Indirect method.*

(A) Preparation of Phenylhydrazones.[1]

Carbonyl compounds combine with phenylhydrazine forming water and phenylhydrazones,

$$C_6H_6NH \cdot N : CRR_1;$$

dihydrazones, with the hydrazine groups linked to neighboring carbon atoms, are termed osazones. The reaction usually takes place most readily in dilute acetic

---

[1] E. Fischer, B. **16**, 661, 2241, foot-note; **17**, 572; **22**, 90.

acid solution, often at the ordinary temperature, almost always by heating on the water-bath. Frequently it is advisable to allow the reaction to proceed at the ordinary temperature in presence of concentrated acetic acid, which acts as a dehydrating agent and in which the phenylhydrazones, as a class, are sparingly soluble.' E. Fischer dissolves or suspends the substance in water or alcohol, and adds, in excess, a mixture of phenylhydrazine hydrochloride (1 part) and crystallized sodium acetate (1.5 parts) dissolved in water (8–10 parts). Free mineral acids must be neutralized by means of sodium hydroxide or sodium carbonate, as their presence hinders the reaction; the presence of nitrous acid is particularly hurtful and it must be removed by means of carbamide, as otherwise it reacts with the phenylhydrazine and forms diazobenzene imide and other oily products. Confusion may also be caused by the production of acetylphenylhydrazine from the dilute acetic acid.[2]

The phenylhydrazones gradually separate from the solution of their components in an oily or crystalline form, and, in the latter case, are purified by recrystallization from water, alcohol, or benzene.

It is often desirable to heat the compound under investigation with free phenyhydrazine, and increased pressure may be used if there is no danger of phenylhydrazides being formed.[3] The product is poured into water, the phenylhydrazone removed by filtration, washed with dilute hydrochloric acid to free it from excess of phenylhydrazine, and recrystallized; in some

---

[3] M. 14, 395.

cases glycerol is employed for washing, the last portions being removed by water.[1] Aliphatic ketones react readily in ethereal solution, and the water which is produced may be absorbed by recently ignited potassium carbonate or calcium chloride. In the case of ketophenols or ketoalcohols the hydroxyl group should be acetylated before treatment with phenylhydrazine; acids are usually used in the form of esters, but the sodium salt is sometimes employed[2] and the condensation promoted by the addition of a mineral acid.[3] Hydrazones may also be prepared from oximes.[4] The carbonyl group in many lactones and acid anhydrides condenses with phenylhydrazine,[5] but not with hydroxylamine;[6] on the other hand, many quinones, such as anthraquinone, do not react with phenylhydrazine or only with one molecular proportion, as in the case of naphthoquinone and phenanthraquinone, whilst some, such as benzoquinone and toluquinone, oxidize it to benzene.[7] Ortho-disubstituted ketones frequently do not react with phenylhydrazine,[8] and certain unsaturated ketoalcohols, such as ethylic acetoacetate[9] and ethylic camphoroxalate,[10] yield monophenylhydrazides, the ketonic group being un-

affected. Hydroxyketones and aldehydes of the aliphatic series yield phenylosazones, a portion of the phenylhydrazine being simultaneously reduced to aniline and ammonia.[3]

A method has been described for the purification of commercial phenylhydrazine.[4]

(B) Preparation of Substituted Hydrazones.

The chief substitution product of phenylhydrazine which has hitherto been employed for the preparation of phenylhydrazones is the parabromo-derivative.

Preparation of Parabromophenylhydrazine.[5] Phenylhydrazine (20 grams) is poured into hydrochloric acid (200 grams, sp. gr. = 1.19) and the precipitated salt uniformly distributed throughout the liquid, which is cooled to 0°; bromine (22.5 grams) is now dropped in, the addition occupying 10–15 minutes, the liquid being well shaken during this time. After remaining during twenty-four hours the precipitate is removed, washed with a little cold hydrochloric acid, dissolved in water, and treated with sodium hydroxide in excess. The base separates in flocculent crystals which are extracted with ether, the ether evaporated, and the residue recrystallized from water. The hydrochloric acid mother liquor contains bromodiazobenzene chloride, which is reduced by the addition of stannous chloride (60 grams); the precipitate is separated, washed with concentrated hydrochloric acid, and treated with water and alkali, the base being collected and purified

- - - - - - - - - - - - - - - - - -

[5] Michaelis, *Ibid.* 26, 2190.

in the manner described above. The yield is 80 per cent. Bromophenylhydrazine requires to be protected from light and air; it should be kept in the dark in well-stoppered colored bottles from which the air has been displaced by carbonic anhydride or coal-gas. In these circumstances, if the compound has been highly purified and dried, it may be retained for years without change; colored specimens may be readily purified by recrystallization from water, to which a few drops of sodium hydroxide should be added. The pure compound melts at 107°–109°, the acetyl derivative at 170°.[1]

Substituted Phenylhydrazones.

Parabromophenylhydrazine is well adapted for the identification of certain sugars, such as arabinose, and has also been used in the investigation of ionone and irone;[2] it is generally employed in acetic acid solution, care being taken to prevent the liquid from boiling, as, in these circumstances, acetyl parabromophenylhydrazine is formed.[3]

Paranitrophenylhydrazine also gives well defined condensation products with many aldehydes and ketones which serve for their identification. The reaction usually proceeds in aqueous solution with the hydrochloride, but the free base in alcohol or acetic acid may be employed.[5]

In addition the following substituted phenylhydrazines have been used for the production of

[1] Tiemann and Krüger.   [2] E. Fischer, B. 24, 4221, foot-note.

phenylhydrazones: *dibromo-*, *symmetrical tribromo-*, *tetrabromo-*, *parachloro-*, *pariodo-*, and *metadiiodo-*,[1] whilst some derivatives of *diphenylhydrazine* have also been described.[2]

(C) Indirect Method.[3]

This method depends on allowing the aldehyde or ketone to react with excess of phenylhydrazine; the excess, together with any hydrazide, is then oxidized by means of boiling Fehling's solution, the liberated nitrogen being collected; phenylhydrazones are not decomposed by this treatment.

The *reagents* required are as follows:

Copper sulphate solution (70 grams Cu So$_4$.5H$_2$O in 1 liter). *Alkaline solution of sodium potassium tartrate*, made by dissolving 350 grams of the tartrate, and 260 grams potassium hydroxide in 1 liter; these two solutions are mixed in equal volumes to form the Fehling's solution.

Sodium acetate (10 per cent solution).

Phenylhydrazine hydrochloride (5 per cent solution.) The *analysis* is made by mixing the compound under examination (0.1–0.5 gram) with an accurately measured quantity of the phenylhydrazine hydrochloride solution (1 part) and the sodium acetate solution (1½ parts) in a 100 cc measuring flask. The phenylhydrazine hydrochloride is taken, if possible, in quantity sufficient to yield 15–30 cc nitrogen. Water is now added to the mixture in the flask so as to make the volume about 50 cc, and the liquid is heated on the

---

[1] A. Neufeld, Ann. 248, 93.   [2] R. Overton, B. 26, 10.

[3] H. Strache, M. 12, 524; 13, 299, Benedikt and Strache, *Ibid.* 14, 270.

water-bath during 15–30 minutes; it is then cooled, diluted to the mark, well shaken, 50 cc transferred to the dropping funnel T, Fig. 8, and the determination

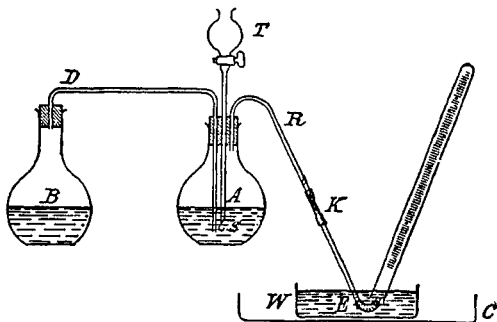

Fig. 8.

conducted in the manner described below. The flask A has a capacity of 750–1000 cc, and contains 200 cc of Fehling's solution, which is boiled whilst a rapid current of steam is blown in from the flask B. The tubes D and R must be flush with the rubber stoppers so as to promote the removal of air. The tube R is in two pieces, joined by the rubber tube K; its lower end is covered with a piece of rubber-tube E and dips below water in the dish W. The current of steam is continued until the bubbles of gas collected are very small, it is impossible, in a reasonable time, to remove all the air and a titration of the phenylhydrazine hydrochloride solution is made, previous to the actual determination, so as to allow for this error. 1 gram of the salt eliminates about 155 cc nitrogen, therefore, for the titration, 10 cc of the solution is accurately measured out, mixed with the needful

proportion of sodium acetate solution, diluted to 100 cc, and 50 cc transferred to the dropping funnel; the end of this is drawn out at S and cut off at an angle so as to avoid the collection of bubbles of gas; before the funnel is fixed in place the stem is filled with water. When the greater portion of the air has been removed from the apparatus in the manner described above, the phenylhydrazine salt is allowed to mix with the Fehling's solution, care being taken to prevent the water flowing from W into A. When all has been added the funnel is washed out twice with hot water, which is, of course, also allowed to run into A. If the boiling is sufficiently brisk the evolution of nitrogen is completed in 2–3 minutes. As soon as the bubbles are as small as those of the air at the commencement of the experiment the heating is stopped, the hot water in W replaced by cold, the excess escaping into the dish C and the measuring tube removed to a cylinder of cold water. The actual determination is made immediately after the completion of the blank experiment and, if necessary, repeated a second or third time; since 200 cc Fehling's solution readily liberates 150 cc nitrogen, the quantity taken in A amply suffices for three or four carbonyl determinations.

As benzene is produced during the oxidation of the phenylhydrazine, a drop of it will be found floating on the surface of the water inside the measuring tube; this may be allowed for in measuring the gas or it may be removed. In the former case a little more benzene is introduced into the tube by means of a bent pipette, and, after remaining during a short time, the volume

of nitrogen is read off in the ordinary manner; its reduction to 0° and 760 mm may be made by the help of the following table, the values in the second column being subtracted from the observed height of the barometer:

Temperature.	Tension of benzene + water.
15° C.	72 7 mm.
16	76.8
17	80.9
18	85.2
19	89.3
20	93.7
21	98.8
22	103.9
23	109.1
24	114.3
25	119.7

The values given above are in part obtained by interpolation from Regnault's results and are therefore subject to error; for this reason, and on account of the high vapor tension of benzene its removal is advisable.[1] To accomplish this alcohol is added to the tube of nitrogen, which is placed in a cylinder of about its own length filled with water (Fig. 9). A glass tube 5 mm. in diameter is bent into the form of a U as shown in the figure, the smaller limb terminating in a jet and being of such length that, when the bent
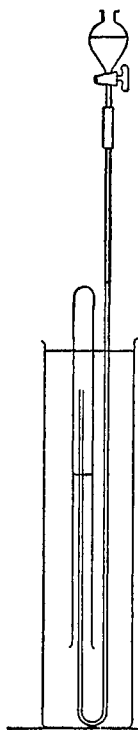

Fig 9.

portion rests on the bottom of the cylinder, the jet is
several cm below the surface of the water. The longer
limb rises about 40 cm above the surface of the water
and is connected at the end by means of a piece of
thick walled rubber tube with a dropping funnel. The
U tube is completely filled with water and placed in
the position shown in the figure. Alcohol (about
200 cc) is now allowed to flow from the funnel
into the measuring tube; it issues from the jet in
a fine stream and absorbs the benzene vapor pres-
ent in the nitrogen as well as that floating on the
water; the alcohol is removed in a similar manner by
washing with at least 400 cc water, and the tube of
nitrogen then removed to another cylinder of water,
where, after a suitable interval, the volume of gas is
read. The amount of carbonylic oxygen O is ob-
tained from the volume of nitrogen, corrected to $0°$
and 760 mm, by the expression : $O = (g.V. - 2V_0.)$.

$$0.0012562 \cdot \frac{15.96}{28.02} \cdot \frac{100}{s}\% = () = (g.V. - 2V_0 \frac{0.07178}{s} \cdot \%,$$

where g is the weight of phenylhydrazine hydro-
chloride taken, V the volume of nitrogen evolved by
1 gram of this salt, S the weight of the compound em-
ployed, and V_0 the volume of nitrogen obtained at
$N. T. P.$ The theoretical value of V is 154.63cc, but
the value employed in the calculation is that obtained
in the blank experiment.

If the phenylhydrazone is in soluble in water or
dilute alcohol, or if sparingly soluble phenylhy-
drazides are formed, the preparation of the phenylhy-
drazone must be made in alcoholic solution; in this

case the weight of the column of liquid in the funnel
T, Fig. 8, will not be sufficient to overcome the
pressure of steam in the flask A. This difficulty may
be surmounted by fitting the open end of the funnel
with a rubber stopper, carrying a tube and stop-cock.
By blowing through the tube the alcoholic liquor is
forced into the flask, but great care is necessary, as
the sudden evolution of alcoholic vapor may eject
liquid from flask A to B, or may even lead to an ex-
plosion. A second objection to the use of alcohol is
that, at its boiling-point, ketones do not always react
quantitatively with phenylhydrazine. Both difficulties
may be overcome by the use of recently boiled amylic
alcohol as solvent, the portion of it which passes over
with the nitrogen being subsequently removed simul-
taneously with the benzene, and in the same manner,
by washing with alcohol and water.

(2) PREPARATION OF OXIMES.[1]

In the preparation of oximes the hydroxylamine is
employed in the form of the *free base*, the *hydro-
chloride*, as *potassium hydroxylaminesulphonate*, or
zinc dihydroxylamine hydrochloride. *Aldoximes* are
obtained by treating aldehydes with an equimolecular
proportion of hydroxylamine hydrochloride in con-
centrated aqueous solution, adding sodium carbonate
(0.5 mol.), and allowing the mixture to remain at the
ordinary temperature during ½-8 days. The oxime
is extracted with ether, the solution dried over calcium

---

[1] V. Meyer and Janny, B. **15**, 1324, 1525. Janny, *Ibid.* **15**,
2778; **16**, 170.

chloride, and, after the removal of the ether, the residue rectified. An aqueous-alcoholic solution is used for aldehydes insoluble in water, and those that are readily oxidizable, such as benzaldehyde, are treated in flasks from which the air has been removed by means of carbonic anhydride.[1] Oximes of the carbohydrates, which are so readily soluble in water that they cannot be separated from the inorganic salts resulting from the use of hydroxylamine hydrochloride and sodium carbonate or sodium hydroxide, are treated with the calculated quantity of free hydroxylamine in alcoholic solution; after several days the oxime gradually crystallizes out.[2] Alcoholic solution of hydroxylamine is prepared by intimately mixing the hydrochloride with the necessary quantity of potassium hydroxide together with a little water, and then adding absolute alcohol, the clear liquid is afterwards separated from the precipitated potassium chloride.[3] The solution gradually acquires a slight yellow color,[4] which may be obviated by substituting sodium ethoxide for the potassium hydroxide.

Ketoximes are usually formed less readily than the aldoximes; for their preparation the ketone is mixed with sodium acetate and hydroxylamine hydrochloride in aqueous or alcoholic solution in the necessary proportions, and the liquid heated on the water-bath during 1–2 hours, or the ketone, in alcoholic solution, may be heated in a sealed tube with the hydrochloride at 160°–180° during 8–10 hours,[5] but sometimes in

[1] Petraczek, B. **15**, 2783.   [2] Wohl, *Ibid.* **24**, 994.   S., p. 367.
[3] Volhard, Ann. **253**, 206.   [4] Tiemann, B. **24**, 994.
[5] Homolka, *Ibid.* **19**, 1084.

these circumstances, instead of the oximes derivatives of them are formed by intramolecular rearrangement.'[1] In many cases it is highly advantageous to allow the carbonyl derivative and the hydroxylamine to react in strongly alkaline solution; the proportions which usually give the best results are ketone, in alcoholic solution (1 mol), hydroxylamine hydrochloride (1.5–2 mol), alkaline hydroxide (4.5–6 mol); the last two are dissolved in the smallest requisite quantity of water.[2] The reaction is often completed at the ordinary temperature in a few hours; occasionally heating on the water-bath is desirable. This method cannot of course be used with ketones or aldehydes that are attacked by alkali, nor in the preparation of dioximes which readily change into their anhydrides in the presence of alkali. In such cases an acid liquid may be employed. Quinone furnishes an example of this. In alkaline solution it is reduced by hydroxylamine to hydroquinone, whilst in aqueous solution, in presence of hydrochloric acid and hydroxylamine hydrochloride, a dioxime is formed.[3] Some compounds, such as phenylglyoxalic acid, yield oximes both in alkaline and acid solution.[4] Oximes of ketonic acids may be obtained by treating the alkali salt in neutral aqueous solution with hydroxylamine hydrochloride; the precipitation of oxime usually commences at once, especially if the liquid is warmed.[5] Sometimes it is advisable to convert the acid into its methyl ester and

[5] Bamberger, *Ibid.* **19**, 1430.

avoid the use of excess of hydroxylamine hydrochloride so as to prevent the formation of nitriles.'

Potassium hydroxylamine sulphonate, supplied by the "Badischen Anilin- und Sodafabrik," under the name "Reducirsalzes," has been employed, in aqueous-alcoholic solution, for the preparation of oximes; [2] in presence of free alkali it is hydrolysed, and the liberated hydroxylamine acts in the nascent state on the carbonyl compounds.[3] It also possesses the advantage of cheapness.

Zinc dihydroxylamine hydrochloride, $ZnCl_2.2NH_2OH$, has been used chiefly for the preparation of ketoximes [4] as its resolution into hydroxylamine and anhydrous zinc chloride facilitates the elimination of water. It is prepared [5] by adding zinc oxide (1 part) to hydroxylamine hydrochloride (2 parts) in boiling alcoholic solution. The boiling is continued in a reflux apparatus for a few moments, and the liquid allowed to cool. The compound is deposited as a crystalline powder which dissolves sparingly in water or alcohol, but readily in solutions of hydroxylamine hydrochloride.

Ortho- and paraquinones and metadiketones cease to react with hydroxylamine if several atoms of hydrogen in the ortho-position are replaced by haloïd atoms or alkyl groups.[6] Aromatic ketones of the formula $(CH_3.C)_2C.COR$, where $R =$ phenyl or an

alcohol radicle, are also incapable of forming oximes;[1] indeed, the presence of carbonyl, which does not yield oximes, in such compounds as acids,[2] amides,[3] or esters[4] may, by the production of hydroxamic acids, lead to erroneous results. The statement that alkyl salicylates and hydroxylamine give salicylhydroxamic acid requires further investigation.[4] The unsaturated ketoalcohol camphoroxalic acid

$$C_8H_{14}{<}{\substack{C:C.OH.CO.OH\\CO}}$$
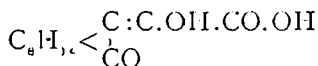

yields an additive compound

$$C_8H_{14}{<}{\substack{CH.C.OH.CO.OH\\CO\ \ NH.OH}}$$
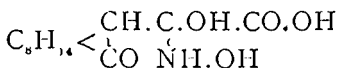

with hydroxylamine,[5] and it has been subsequently shown that certain unsaturated ketones, such as phorone, behave in a similar manner.[6]

(3) PREPARATION OF SEMICARBAZONES.[7]

The formation of well-crystallized derivatives of semicarbazide has proved extremely useful in the investigation of terpene compounds which often yield liquid oximes, and phenylhydrazones that only crys-

tallize with difficulty and readily undergo decomposition.

Preparation of Semicarbazide Salts.

(A) *Semicarbazide Hydrochloride*

$$NH_2.CO.NH.NH_2.HCl$$

is prepared from

(a) *Hydrazine sulphate*;[1]
(b) *Nitrocarbamide*.[2]

(a) Hydrazine sulphate (13 grams) is dissolved in water (100 cc), and neutralized with dry sodium carbonate (5.5 grams), when cold potassium cyanate (8.8 grams) is added and the solution allowed to remain overnight. A small quantity of hydrazodicarbonamide, $NH_2.CO.NH.NH.CO.NH_2$, s deposited which is somewhat augmented on acidifying with dilute sulphuric acid. The amide is removed and the acid liquid well shaken with benzaldehyde; the precipitate of benzal-semicarbazone which forms is separated and well washed with ether. It is now carefully heated on the water-bath, in portions of 20 grams, with concentrated hydrochloric acid (40 grams), sufficient water being added to cause the hot liquid to become clear; the benzaldehyde is removed by repeatedly extracting the hot liquid with benzene; when cold the aqueous solution deposits small needles of semicarbazide hydrochloride, which are removed, dried, and recrystallized from dilute alcohol. The purified compound forms prisms

[1] Thiele and O. Stange, B. **28**, 32.
[2] Thiele and Heuser, Ann. **288**, 312.

which decompose at 173°.   The mother-liquors yield
a further quantity of the benzal derivative when treated
with benzaldehyde.

(b) Commercial nitrocarbamide (225 grams) is mixed
with concentrated hydrochloric acid (1700 cc), a little
ice added, and the liquid made into a paste by the
successive additions of small quantities of zinc-dust
and ice; constant stirring is necessary, and the tem-
perature must not exceed 0°.   The operation may be
carried out in an enamelled dish cooled by means of
a freezing mixture; when it is completed the product
is allowed to remain for a short time, the excess of
zinc-dust removed, and the filtrate saturated with
sodium chloride.   Sodium acetate (200 grams) is now
added, together with acetone (100 grams), and the
liquid placed on ice or in a freezing mixture.   In the
course of several hours a double salt of zinc chloride
and acetone semicarbazide crystallizes out, it is
collected and washed first with sodium chloride solu-
tion and finally with a little water.   The yield is
40—55 per cent.   The zinc compound (200 grams) is
digested with concentrated ammonium hydrate (350 cc)
and after some time the liquid is filtered; the residue
consists of acetone semicarbazone, which is converted
into semicarbazide salts in the manner described above
for the benzal derivative.   Many ketones do not
readily react with semicarbazide hydrochloride and
the products obtained from some may contain chlorine;
in such cases semi-carbazide sulphate should be
employed.

(B) *Preparation of Semicarbazide Sulphate.*[1]

The filtrate from hydrazodicarbonamide, prepared in the manner described above, is cautiously made alkaline and shaken with acetone; the acetone semicarbazone which is deposited is mixed with alcohol, and treated with the calculated quantity of sulphuric acid; the sulphate crystallizes out and is purified by washing with alcohol.

Preparation of Semicarbazones.[2]

Semicarbazide hydrochloride, dissolved in the minimum quantity of water, is mixed with the calculated amount of potassium acetate in alcoholic solution, and the ketone added, together with water and alcohol sufficient to give a clear homogeneous liquid. This is allowed to remain until the completion of the reaction, which is recognized by the deposition of crystals when the mixture is diluted with water, and, as in the case of hydroxylamine, may require from a few minutes to four or five days. Sometimes it happens that the deposit produced is oily and only solidifies after several hours. The use of semicarbazide sulphate is illustrated by the preparation of ionone semicarbazone, which cannot be obtained from the hydrochloride. The sulphate is used in a finely divided form and added to glacial acetic acid in which the equivalent quantity of sodium acetate has been dissolved; after remaining at the ordinary temperature during twenty-four hours, the solution of ionone is

---

[1] Tiemann and Krüger, B. **28**, 1754.   [2] Baeyer, *Ibid.* **27**, 1918.

added, and the liquid allowed to remain three days longer. The product is poured into a considerable volume of water, extracted with ether, and the ether freed from acetic acid by treatment with sodium carbonate solution. After drying and removal of the ether the residue is treated with ligroin to remove some impurities, and the remaining product crystallized from a mixture of benzene and ligroin.

Should a ketone not yield a crystalline semicarbazide it is advisable to treat it with amidoguinadine picrate, as the resulting compounds are distinguished by the ease with which they crystallize.

(4) PREPARATION OF AMIDOGUINADINE DERIVATIVES.[1]

Preparation of Amidoguinadine Salts.[2]

Nitroguinadine (208 grams) is mixed with zinc-dust (700 grams) and sufficient ice and water to form a stiff paste; to this commercial glacial acetic acid (124 grams), diluted with its own volume of water, is added, the mixture is well stirred, and great care taken to add ice so that during the 2–3 minutes required for the addition of the acid the temperature shall not exceed 0°. The temperature is now allowed to rise gradually to 70°; at this stage the mixture is viscid and has a yellow color due to an intermediate product. The temperature is maintained at 40°–45° until a little of the filtered liquid ceases to yield a red color with sodium hydroxide and a ferrous salt. The conclusion of the operation is usually in-

---

dicated by evolution of gas and the formation of a
frothy scum on the surface of the liquid. The product
is filtered, the residue well washed with water, the
washings and filtrate mixed with hydrochloric acid
sufficient to liberate the acetic acid, and the whole
concentrated to the smallest possible bulk; it is then
treated with alcohol, again evaporated to expel water,
and the solid boiled out with alcohol; this, when
cold, deposits amidoguinadine hydrochloride, which is
further purified by recrystallization from alcohol to
which animal charcoal has been added. The pure
salt melts at 163°.

Preparation of Amidoguinadine Bicarbonate.[1]

The liquid obtained by the reduction of nitroguina-
dine with zinc-dust and acetic acid is maintained
slightly acid with acetic acid, evaporated to about
500 cc, cooled, and treated with concentrated sodium
or potassium bicarbonate solution to which a little
ammonium chloride has been added to prevent the
deposition of any zinc. The amidoguinadine salt is
completely precipitated in twenty-four hours; it is
sparingly soluble in hot water but suffers decomposi-
tion, and when slowly heated it melts and decom-
poses at 172°.

The nitrate and the normal and hydrogen sulphates
are prepared in a similar manner.

---

[1] Thiele, Ann. **302**, 333.

Preparation of Amidoguinadine Picrate Derivatives.

Amidoguinadine hydrochloride is dissolved in a small quantity of water containing a trace of hydrochloric acid and the ketone added together with sufficient alcohol to give a clear solution. The reaction is completed by boiling for a short time. The product is treated with water and sodium hydroxide solution in excess, and the liquid base extracted by means of ether. The ethereal solution is separated, the ether removed, the residual oil suspended in water and treated with picric acid in aqueous solution, the picrate is quickly deposited in granular crystals which are purified by recrystallization from concentrated or dilute alcohol.

Some carbohydrate derivatives of amidoguinadine are known.[1]

PARAMIDODIMETHYLANILINE DERIVATIVES.

Condensation products of aldehydes and paramidodimethyl aniline may be prepared by mixing the constituents with or without the addition of alcohol. The temperature of the liquid rises spontaneously, and the condensation product usually separates in crystals.[2]

[1] Wolff and Herzfeld, *Z. Rüb. 1895*, 743. Wolff, B. **27**, 971; **28**, 2613.

[2] A. Cahn, *Ibid.* **17**, 2938. The literature of this subject is given in M. and J. II, p. 515.

DETERMINATION OF THE AMINO $\overset{I}{N}H_2$; NITRILE $\overset{I}{C}N$; AMIDE $\overset{I}{C}O.NH_2$; IMIDE $\overset{II}{N}H$; METHYL IMIDE $\overset{II}{N}.CH_3$; AND ETHYL IMIDE $\overset{II}{N}.C_2H_5$ GROUPS.

DETERMINATION OF THE AMINO GROUP ($\overset{I}{N}H_2$).

Different methods are employed for the determination of the amino group according to whether the compound is an aromatic or aliphatic amine.

(A) Determination of Aliphatic Amino Groups.

These are determined:

(1) *By means of nitrous acid.*

(2) *By analysis of the salts and double salts.*

(3) *By acetylation.*

(1) *Nitrous Acid Method.*—Aliphatic amines react with nitrous acid in accordance with the equation

$$RNH_2 + HNO_2 \longrightarrow ROH + N_2 + H_2O.$$
The first method suggested for the determination of the nitrogen consisted in liberating it in an atmosphere of nitric oxide, which was then absorbed by means of ferrous sulphate solution.[1] The following process is much more convenient. The substance, dissolved in

---

[1] R. Sachsse and W. Kormann, Landwirthsch. Vers.-Stationen, **17**, 321. Z. anal. Ch. **14**, 380.

just sufficient dilute sulphuric acid to give a neutral solution, is placed in a flask provided with a trebly bored stopper. If possible a distillation bulb should be employed having a capillary tube fused to it. A dropping funnel is fitted to the stopper of the flask, the leg being drawn out, bent upwards, and passed below the surface of the liquid; it is filled with distilled water at the commencement of the experiment. The third tube of the flask, or the side tube of the distillation bulb, is fitted by means of an airtight stopper almost to the bottom of a second distillation-bulb. This has its side tube suitably bent, and connected with a Liebig's potash bulb filled with potassium permanganate solution (3 per cent) containing sodium hydroxide (about 1 gram). The gas delivery-tube is attached to the potash bulbs and dips below the mouth of the measuring vessel, which is half filled with mercury and half with potassium hydroxide (sp. gr. = 1.4). The air is displaced from the apparatus by a slow current of carbonic anhydride, which may be obtained pure and free from air by dropping dilute sulphuric acid (50 per cent. sp. gr. = 1.4) into a concentrated solution of potassium carbonate (sp. gr. = 1.45–1.5).' When the air is expelled the measuring tube is placed in position and a slight excess of potassium nitrite solution added by means of the dropping-funnel. The reaction is completed by heating on the water-bath and the addition of a little dilute sulphuric acid.

(2) *Analysis of Salts and Double Salts.*—The prep-

' Fr. Blau, M. **13**, 280.

aration of most of these is too well known to require comment. Of the simple salts the *hydrochlorides* some-times can only be induced to crystallize in a state of purity by the action of anhydrous hydrogen chloride on a solution of the base in ether free from alcohol and moisture.   The *chromate* and *picrate*,' especially the latter, usually crystallize readily.   The *mercuri-chloride*, $RHgCl_2$, has occasionally been of service in cases where the *auro-chloride* or *platino-chloride* are oily or unstable (cf. pp. 89, 94).

(3) *Acetylation.*—This is described in the next section on the acetylation of the aromatic amines.

(B) Determination of Aromatic Amino Groups.

The following methods are employed for the determination of primary aromatic amines:

(1) *Titration of the salts.*
(2) *Preparation of diazo derivatives.*
　　(*a*) *By conversion into an azo dye.*
　　(*b*) *Indirect method.*
　　(*c*) *Azoimide method.*
　　(*d*) *By means of the Sandmeyer-Gattermann reaction.*
(3) *Analysis of salts and double salts.*
(4) *Acetylation.*

(1) TITRATION OF THE SALTS.[2]

(I) Salts of aromatic amines, in aqueous or alcoholic solution, give an acid reaction with rosolic acid or

---

[1] Delépine, Bull. **15**, 53.

[2] Menschutkin, B. **16**, 316.

phenolphthalein. The salt, preferably the hydro-
chloride or sulphate, is dissolved in water or dilute
alcohol, phenolphthalein added, and the titration
carried out in the ordinary manner with potassium
hydroxide.

(II) Many free bases may be directly titrated with
hydrochloric acid, methyl orange being used as an
indicator.

(2) PREPARATION OF DIAZO-DERIVATIVES.

(a) *Conversion of the Base into an Azo Dye.*[1]

The base, for example aniline (0.7–0.8 gram), is
dissolved in hydrochloric acid (3 cc) and diluted with
water and ice to 100 cc. A titrated solution of " R-
salt," sodium 2 : 3 : 6 naphtholdisulphonate, is pre-
pared, of such strength that a liter is equivalent to about
10 grams of naphthol. The solution of the hydro-
chloride is cooled to 0°, sodium nitrite added in quantity
equivalent to the aniline or other base present, and
the mixture gradually poured into a measured quantity
of the sulphonate solution which has been treated
with sodium carbonate in excess. The dye produced
is precipitated by means of sodium chloride, filtered,
and the filtrate tested with diazobenzene chloride so-
lution and R-salt to determine whether the latter or
the base is in excess. By repeating the experiment
it is possible to find the volume of R-salt solution
necessary to combine with the diazo-derivative of the
base originally taken.

---

[1] Reverdin and De la Harpe, Ch. Zig. **13**, I. 387, 407; B. **22**, 1004.

The following method has been applied to aniline, ortho- and paratoluidine, metaxylidine, and sulphanilic acid.[1] A known quantity of the base is diazotized and made made up to a certain volume; it is then immediately added from a burette to a solution of "Schäfer's salt," sodium 2 : 6-naphthol sulphonate, of known strength, which has been mixed with sodium chloride and a few drops of ammonium hydroxide, the addition being continued so long as a precipitate forms. The end point is determined by bringing a drop of the clear supernatant liquor on to filter paper and allowing it to come into contact with a drop of the diazo-solution. The progress of the reaction can be followed by the intensity of the red color produced at the point of contact of the two liquids on the paper. Towards the end of the operation the color is only visible in the middle of the moist circle. In the case of readily soluble dyes, such as that given by sulphanilic acid, the paper must be covered with a thin crust of sodium chloride and the test portions allowed to fall on to it; more sodium chloride must also be added to the naphtholsulphonate solution.

(b) *Indirect Method.*

This is extensively employed for technical purposes and consists of an inversion of a method for the determination of nitrous acid.[2] The base is treated with three times its weight of hydrochloric acid and the mixture dissolved in so much water that the solution

---

[1] R. Hirsch, B. **24**, 324.

[2] A. G. Green and S. Rideal, Ch. N. **49**, 173.

contains 0.01 to 0.1 gram equivalent of the base. The solution is maintained at 0° by means of ice, and titrated with sodium nitrite solution, potassium iodo-starch paper being used as indicator; the operation is ended when a drop of the mixed liquids gives a blue coloration with the paper. The nitrite solution should be about $N/10$. It is prepared[1] by dissolving the nitrite in 300 parts of cold water and is titrated by adding $N/10$ potassium permanganate solution until a distinct permanent red coloration is obtained; two or three drops of dilute sulphuric acid are now added, then immediately excess of the permanganate, the liquid is made strongly acid with sulphuric acid, heated to boiling, and the excess of permanganate determined by means of $N/10$ oxalic acid solution.

(c) *Azoimide Method.*[2]

This is specially applicable to compounds containing amino groups linked to different nuclei. The azo-imides are prepared by the action of ammonia on the diazoperbromides[3] and, on account of the large content of nitrogen in the former, their analysis is pecul-iarly well adapted for the determination of the num-ber of diazotisable groups in the molecule. Details of the method of preparing azoimides have been given by various chemists[4].

[4] Nölting, Grandmougin, and O. Michel, B. 25, 3328. Curtius and Dedichen, J. pr. [2], 50, 250.

(d) *Sandmeyer*[1]*-Gattermann's*[2] *Reaction.*

The determination of the amino group is often conveniently accomplished by converting it into the diazo-derivative and replacing the nitrogen by chlorine; as a rule the diazo-compound is not isolated. The following example[3] will serve to illustrate the method: Metanitraniline (4 grams) and concentrated hydrochloric acid, sp. gr. = 1.17 (7 grams), are dissolved in water (100 grams), and 10 per cent cuprous chloride solution (20 grams) added; the mixture is heated almost to boiling in a reflux apparatus, and sodium nitrite (2.5 grams), dissolved in water (20 grams) is gradually run in by means of a dropping funnel, the mixture being well shaken during the addition. Nitrogen is evolved and a heavy brown oil collects which solidifies when cooled with ice and is purified by distillation. As a rule these chloro-derivatives are volatile with steam; if not they are purified by means of ether or benzene.

The above method is the one originally proposed by Sandmeyer; by means of it chloro-compounds may be readily obtained from diamines which cannot be diazotised in the ordinary manner. The cuprous chloride employed is prepared by boiling crystallized copper sulphate (25 parts) and anhydrous sodium chloride (12 parts) with water (50 parts); some sodium sulphate crystallizes out, and when the reaction is completed the product is mixed with concentrated hydrochloric acid (100 parts) and copper turnings

---

[1] B. **17**, 1633.   [2] *Ibid,* **23**, 1218.   [3] *Ibid,* **17**, 2650.

(13 parts), the mouth of the flask is loosely closed and the mixture boiled until the liquid becomes color-less. Sufficient concentrated hydrochloric acid is now added to bring the weight of the mixture to 203.6 parts, since only 6.4 parts of the copper actually dis-solve, 197 parts of solution are obtained which con-tains 0.2 gram molecules of Cu. Cl. The filtered solution may be retained a considerable time in a well closed bottle containing carbonic anhydride.[1]

Cupric chloride is reduced to cuprous chloride by hypophosphorus acid,[2] hence, in place of the cuprous chloride solution prepared according to the foregoing method, a mixture of hydrochloric acid, copper sul-phate solution, and sodium hypophosphite may be employed.[3]

The use of finely divided copper instead of cuprous chloride has been suggested;[4] amongst other advan-tages the reaction proceeds at the ordinary temperature, and the yield is frequently improved. The copper is prepared by adding zinc-dust, through a fine sieve, to a cold saturated solution of copper sulphate until only a faint blue color remains, the product is well washed by decantation with large quantities of water, the remaining zinc removed by digestion with highly di-lute hydrochloric acid, and the copper filtered and washed with water until neutral; it is preserved in the form of a paste in well-closed bottles. The follow-ing example will illustrate the method of work-ing: Aniline (3.1 grams) is mixed with 40 per cent.

[1] Feitler, J. pr. **4**, 68.   [2] A. Cavazzi, Gazz. **16**, 167.

[3] A. Angeli, *Ibid.* **21**, *2*, 258.   [4] Gattermann, B. **23**, 1218.

hydrochloric acid (30 grams) and water (15 cc), the liquid is cooled to 0° and a saturated aqueous solution of sodium nitrite (2.3 grams) quickly added, the liquid being vigorously stirred, preferably by means of a turbine; the reaction is completed in one minute. Finely divided copper (4 grams) is now gradually added to the diazo solution, which is well stirred; the reaction requires 15–30 minutes for completion, this is signalized by the particles of copper ceasing to be carried to the surface of the liquid by the escaping bubbles of nitrogen. The chlorobenzene is removed by steam distillation.

(3) ANALYSIS OF SALTS AND DOUBLE SALTS.

The remarks on the salts of aliphatic amines (p. 83) apply generally to those of the aromatic series; the accumulation of negative groups in their molecules often completely prevents the formation of salts. As a rule the *auro-chloride* contains one atom of gold for each amino group, and the *platino-chloride* one atom of platinum to two amino groups, but amino pyridine platino-chloride has the formula $(C_5H_6N_2)_2.H_2PtCl_6$.[1] Sometimes the *alkyl haloïd salts* are of service, but many primary bases do not form them.[2] In presence of secondary or tertiary amino groups the method yields fallacious results. Certain compounds free from nitrogen may form salts, dimethylpyrone, for example, gives amongst others a platino-chloride $(C_7H_8O_2)_2.H_2PtCl_6$.[3]

[1] M. **15**, 176.   [2] Hofmann, Jahresbericht (*1863*), p. 421.

[3] Collie & Tickle, Journ. Chem. Soc. **75**, 712.

(4) ACETYLATION.

The methods of acetylation described for the deter-mination of hydroxyl (Chapter I) are also applicable to the amino group (cf. acetylation of imides, p. 92).

DETERMINATION OF THE NITRILE GROUP ($\overset{|}{C}:N.$)

The nitrile radicle is determined by hydrolysis, the resulting ammonia or acid being collected.

(*a*) Prolonged boiling with hydrochloric acid is usually sufficient to cause hydrolysis; the product is then treated with alkali in excess, and the ammonia distilled off and determined in the ordinary manner.

(*b*) Should the hydrolysis only take place in the presence of aqueous or alcoholic alkali an apparatus similar to that employed in Zeisel's method for the determination of methoxyl is used (Fig. 1, p. 34). A current of air, freed from carbonic anhydride, is passed through the apparatus, and the bulbs are filled with concentrated alkali solution; the ammonia is most readily determined as the platino-chloride. At the conclusion of the experiment the flask *A* will contain the alkali salt of the acid produced, and may be treated by one of the methods described for the determination of carboxyl (Chapter II).

(*c*) The hydrolysis of nitriles [1] may be hindered by stereo-chemical influences, especially in the case of diortho-substituted compounds,[2] just as the corre-sponding acids etherify with difficulty, or not at all, under the influence of hydrogen chloride. The nitriles

---

[1] M. and J., II, p. 545.

[2] A. W. v. Hofmann, B. **17**, 1914; 18, 1825; Stallburg, Ann. **278**, 209. Cain, B. **28**, 969. V. Meyer and Erb. *Ibid.* **29**, 834, foot-note. Sudborough, Journ. Chem. Soc. **67**, 601.

in question, although they resist prolonged heating at a high temperature in a sealed tube with hydrochloric acid, are all converted into amides by continued boiling with alcoholic potassium hydroxide.[1] The amide is hydrolysed to the acid in the manner described in the following section: Cyanmesitylene[2] requires boiling during seventy-two hours with alcoholic potassium hydroxide, and triphenylacetonitrile[3] needs fifty hours boiling with the same reagent to produce the amide. Some nitriles that are otherwise resistant may be hydrolysed by heating at $120°–130°$ during an hour with 90 per cent sulphuric acid (20–30 parts). The resulting amide is converted into the acid by means of nitrous acid[4] (cf. following section). Unhydrolysable nitriles have also been described.[5]

(*d*) Certain amides may be obtained by the action of alkaline hydrogen peroxide at $40°$ on the nitriles; the resulting compounds are then treated in the manner described in the preceding section.

DETERMINATION OF THE AMIDO GROUP ($\overset{1}{C}O . NH_2$).

The amido group is determined by hydrolysis, in a similar manner to the nitrile group (preceding section). The method employed for the hydrolysis of very stable amides[7] is best illustrated by its application to the preparation of triphenylacetic acid.[8] The

[8] G. Heyl and V. Meyer, B. **28**, 2783.

finely divided amide (0.2 gram) is gently warmed
with concentrated sulphuric acid (1 gram) and the
clear solution cooled in ice, sodium nitrite (0.2 gram),
dissolved in water (1 gram) cooled to 0° is added
very slowly by means of a capillary tube; when the
addition is complete the test-tube containing the
mixture is placed in a beaker of water and gradually
heated.   The evolution of nitrogen commences at
60°–70°, and is completed at 80°–90°; finally the tube
is heated in boiling water for 3–4 minutes, but not
longer.   When cool, ice is added to the liquid, the
precipitated solid collected, and purified by solution in
dilute sodium hydroxide and precipitation with sul-
phuric acid.   It is highly desirable to use the exact
theoretical quantity of sodium nitrite dissolved in the
smallest possible volume of water.[1]   Stereo-chemical
influences are effective in hindering the hydrolysis of
amides as they are that of the nitriles.[2]

DETERMINATION OF THE IMIDE GROUP ($\overset{\text{\tiny H}}{N}$H).

The following methods are employed for the deter-
mination of the imide group:

(1) Acetylation.
(2) Alkylation.
(3) Analysis of salts.
(4) Elimination of the imidogen as ammonia.

(1) ACETYLATION OF IMIDES (SECONDARY AMINES).

Imides may be acetylated by any of the methods
employed for the determination of hydroxyl which are

[1] Sudborough, Jour. Chem. Soc. **67**, 604.
[2] A bibliography of the subject is given in M. and J. II, p. 545.

described in Chapter I. The reaction usually takes place without difficulty, and therefore an indirect method[1] may be utilized. A weighed quantity of the compound (about 1 gram) is placed in a flask, fitted to a reflux apparatus, and acetic anhydride (about 2 grams) quickly added. The anhydride should be added from a suitably stoppered vessel, which is weighed before and after the addition. The mixture is allowed to remain at the ordinary temperature during about thirty minutes, water (50 cc) is then added, and the liquid heated on the water-bath during forty-five minutes; the solution is now cooled, diluted to a definite volume, and titrated with sodium hydroxide of known strength, phenolphthaleïn being used as indicator.

The process was specially worked out for methylaniline, hence, for other imides, the duration of the heating and the temperature require modification according to the readiness with which they react. It may be desirable to heat in a sealed tube, or in a dry closed flask, the mixture being constantly shaken, and the anhydride diluted with ten volumes of dimethylaniline.[2]

(2) ALKYLATION OF IMIDES.

Some imide groups may be methylated by dissolving the compound in alkali and gradually adding methylic iodide; the mixture is constantly shaken and maintained at the ordinary temperature. The method has been extensively employed in the investigation of purin and uric acid derivatives.[3]

[3] E. Fischer, B. 28, 2479; 30, 569, 3094; 32, 453. C. (1897), II. 157.

(3) ANALYSIS OF SALTS.

The remarks on the analysis of salts of primary amines (pp. 83, 89) apply equally to those of secondary ones.

(4) ELIMINATION OF IMIDOGEN AS AMMONIA.

The hydrolysis of the imides is usually carried out by prolonged boiling with hydrochloric acid either in an open vessel or under pressure in a sealed tube. The liquid is then made alkaline, the ammonia or amine volatilized into hydrochloric acid, and the excess of the latter determined by titration or, in some cases, by means of the platino-chloride.

DETERMINATION OF METHYL IMIDE ($\overset{\text{H}}{N}CH_3$).[1]

The hydriodides of methylated bases eliminate methyl iodide at 200°–300° in accordance with the equation $R_2NCH_3.HI \longrightarrow R_2NH + CH_3I$; the iodide may be determined by Zeisel's method (cf. p. 33).

The apparatus employed is identical with that of Zeisel except the vessel in which the substance is heated. This is shown in Fig. 10, and consists of a double flask $a\ b$ connected by means of a cork with the vessel c. The method is modified according to whether one or more alkyl groups are linked to nitrogen, and, in the latter case, whether these are to be
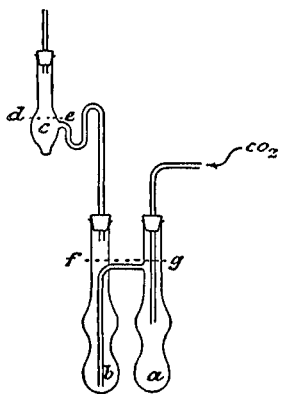

Fig. 10.

[1] J. Herzig and H. Meyer, B. **27**, 319. M. **15**, 613; **16**, 599.

determined successively; finally the presence of alkyloxy groups, in addition to methyl imide, demands special manipulation.

(1) *Determination with only one Alkyl linked to Nitrogen.*

The compound (0.15–0.3 gram) as free base, nitrate, or haloïd salt is placed in the flask a together with sufficient hydriodic acid (sp. gr. = 1.68–1.72) to fill the vessel c to the mark de; the object of this is to retain any volatile basic compounds which might be carried over by the carbonic anhydride. In addition to the acid the flask a also contains ammonium iodide in quantity equal to 5–6 times that of the substance employed. The vessel C is connected directly with the condenser (Fig. 1, p. 34); it should contain a little red phosphorus if much iodine is liberated in a, as is usually the case when nitrates are employed. The flask b is filled with asbestos, a little of which is also placed in a to facilitate the boiling. A more rapid current of carbonic anhydride is used than in the determination of methoxyl, so as to remove the methyl iodide as quickly as possible and prevent its entering into combination with the other compounds produced, consequently two absorption flasks with silver nitrate must always be employed. The heating is done by means of a sand-bath of copper with a sheet-iron bottom; it is divided into two equal portions by a partition, and is of such a shape as to permit the flasks being immersed in the sand up to the line fg. The flask a is first heated, carbonic anhydride being passed through

the apparatus, a portion of the acid distils into b and some into c. Gradually the second chamber of the bath is filled with sand, and b then directly heated. All the acid soon accumulates in c, the carbonic anhydride bubbling through it whilst the flask a contains only the hydriodide of the base. The commencement of the decomposition is indicated by a turbidity in the silver nitrate solution, and it occurs soon after the acid has been expelled from the flask b. The remainder of the experiment is carried out exactly as in the methoxyl determination.

(2) *Determination with two or more Alkyl Groups linked to Nitrogen.*

This is carried out in the manner described in the preceding section; when the operation is completed the apparatus is allowed to cool in a current of carbonic anhydride, c is detached from the condenser, and by cautious tilting the acid poured from it back to b, whence it will pass spontaneously to a. A fresh quantity of silver nitrate is placed in the absorption flasks, and the apparatus is ready to heat again. The operation is repeated until the quantity of silver iodide obtained is equivalent to an amount of alkyl weighing less than 0.5 per cent of the substance employed. It is important to conduct the determinations at the lowest possible temperature, and therefore a thermometer is placed in the sand-bath which is never allowed to exceed, by more than 40°, the temperature (200°–250°) at which the silver nitrate solution first becomes turbid. When several alkyl groups are pres-

ent, it is advisable to use more ammonium iodide than otherwise, about 5 grams in *a*, and 2–3 grams in *b*. Each decomposition requires some two hours for completion, and three such are amply sufficient even though the compound contains three or four alkyls.

(3) *Successive Determination of the Alkyl Groups.*

The alkyl groups may be successively eliminated from feebly basic compounds such as caffeine or theobromine. In place of the vessel previously employed (Fig. 10), the substance is heated in one of the shape shown in Fig. 11. It is immersed in a sand-bath to the mark *ab*; after heating the acid is allowed to flow back to the flask, a little ammonium iodide is added, and the heating repeated,—the operation being performed a third time, with the addition of more ammonium iodide, if three alkyl groups are present.
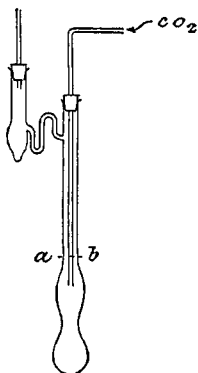

FIG. 11.

(4) *Determination of Methyl Imide in Presence of Methoxyl.*

The methyl imide may be determined in presence of methoxyl by heating the hydriodide alone in the flask *a* (Fig. 10); it is, however, preferable to add to it hydriodic acid (10 cc), and heat the flask in an oil- or glycerol-bath so that scarcely any distils over into *b*. When the operation is ended, which is indicated by the silver nitrate solution becoming clear, the temperature is raised, and the acid distilled off until only

so much remains in *a* as is usually employed for the methyl imide determination (see section 1). During the distillation the silver nitrate solution remains quite clear, and the methoxyl determination is completed. A fresh portion of silver nitrate is taken, the excess of acid removed from *b* and *c*, ammonium iodide added, and the methyl imide determination commenced in the manner described in the preceding sections.

(5) *General Remarks on the Method.*

The purity of the hydriodic acid and ammonium iodide must be ascertained by means of a blank experiment.

The method is applicable to all compounds which can form a hydriodide even though this may not be capable of isolation, and accurate results are obtained by the use of the hydrobromide, hydrochloride, or nitrate. Quantitative results are also obtained in the case of many compounds, such as *n*-ethylpyrroline, methylcarbazole, and dimethylparabanic acid, which do not form salts. The limits of error lie between $+ 3$ and $- 15$ per cent of the total alkyl, consequently the presence or absence of one such group can only be determined with certainty when the theoretical difference in composition for one alkyl exceeds 2 per cent, or, in other words, when the molecular weight of the original methylated compound is less than 650.

In considering the results obtained it is necessary to observe the color of the silver iodide; should this be dark or gray instead of yellow, the error is almost always positive.

100 parts $AgI = 6.38$ parts of CH_3.

DETERMINATION OF ETHYL IMIDE ($\overset{\shortmid\shortmid}{N}C_2H_6$).

The method[1] of determination is exactly the same as that described above for methyl imide.   100 parts Ag I = 12.34 parts of C_2H_6.

DIFFERENTIATION OF THE METHYL IMIDE AND ETHYL IMIDE GROUPS.

The method of determination by means of the alkyl iodides does not, as a rule, distinguish between ethyl imide and methyl imide; in doubtful cases it is necessary to distil a considerable quantity of the hydriodide of the base, and purify and identify the alkyl iodide which is evolved. A second method consists in distilling the base with potassium hydroxide, evaporating the distillate with hydrochloric acid to dryness, separating the organic hydrochlorides from ammonium chloride by means of absolute alcohol, and converting the former into picrates, platinochlorides, etc., which may then be identified; the method must, however, be used with caution, as it may lead to erroneous results.

Chapter V.

DETERMINATION OF THE DIAZO GROUP $(R.N:N.R)$; OF THE HYDRAZIDE RADICLE $(\overset{\shortmid}{N}H.NH_2)$; OF THE NITRO-GROUP (NO_2); OF THE IODOSO-GROUP (IO); OF THE IODOXY-GROUP (IO_2); OF THE PEROXIDE GROUP $\overset{u}{C}\!\!<^{O}_{O}$; IODINE NUMBER.

DETERMINATION OF THE DIAZO GROUP $(R.N:N.R)$.

The aliphatic and aromatic diazo-compounds are differently constituted, hence the methods adapted for their determination are not identical.

(A) Aliphatic Diazo-compounds $\left(C - CH\!\!<^{N}_{N}\right)$.

The following methods are employed:[1]

(1) *Titration with iodine.*

(2) *Analysis of the iodo-derivatives.*

(3) *Determination of the nitrogen in the wet way.*

(1) DETERMINATION OF THE NITROGEN BY TITRATION WITH IODINE.

This reaction takes place in accordance with the equation $CHN_2.COOR + I_2 \longrightarrow CHI_2.COOR + N_2$.

Rather more than the theoretical quantity of iodine is accurately weighed, dissolved in absolute ether, and added, by means of a burette, to a known quantity

---

[1] Curtius, J. pr. **146**, 422.

of the diazo-compound also in ethereal solution; the end of the reaction is indicated by a sharp change in the color of the diazo-compound from lemon yellow to red; towards the conclusion of the titration the reaction is facilitated by warming the liquid on the water-bath. The excess of iodine solution is run into a tared flask, the ether cautiously removed, and the residue weighed. Unless the compound employed is in a high state of purity the change of color in the liquid takes place long before all the nitrogen has been expelled.

(2) ANALYSIS OF THE IODINE DERIVATIVE.

The iodine in the iodo-compound may be determined in the ordinary manner, or the following simpler method, first used in the investigation of diazoacetamide,[1] may be employed. A weighed quantity of the substance is placed in a tared beaker, dissolved in a little absolute alcohol, and iodine added until a permanent red coloration is obtained. The alcohol is volatilized on the water-bath, the excess of iodine removed by cautious heating, and the crystalline residue weighed. In this case also the compound employed must be pure.

(3) DETERMINATION OF THE NITROGEN IN THE WET WAY.

On account of the great volatility of the aliphatic ethereal diazocarboxylates the method of nitrogen

---

[1] Curtius, J. pr, **146**, 423.

determination described on p. 81 cannot be employed.
This difficulty is overcome [1] by the use of the apparatus
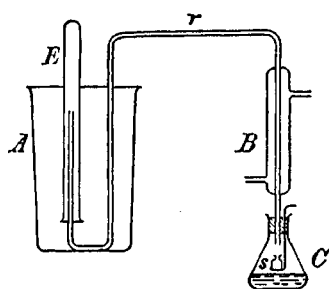

shown in Fig. 12. *A* is a
large gas cylinder contain-
ing water, *r* a capillary tube,
the upper open end of
which rises a little above
the level of the water in
A. *E* is a gas measuring
tube, *B* a small condenser
fitted to the little flask *C*
by means of a rubber stop-

Fig. 12.

per; through this a platinum wire also passes. It is
bent in the manner shown and carries a glass-stoppered
vessel such as is employed in vapor density deter-
minations. The flask *C* is partially filled with well
boiled, highly dilute sulphuric acid, the compound
(about 0.2 gram) weighed into the small vessel *s*, and
the apparatus fitted together air-tight. When the air
in the apparatus is in equilibrium with the atmosphere,
which can readily be observed if a drop of water is
placed in *r*, the volume of air in the endiometer tube
is read off, and the temperature noted. The vessel *s*
is now dropped into the acid, which is gradually heated
to boiling; the decomposition is completed in a few
minutes. The apparatus is allowed to cool com-
pletely, the level of water in and outside the tube *E*
adjusted, and the volume, temperature, and pressure
noted; the difference in volume from the previous
reading gives the quantity of nitrogen evolved. As a

[1] Curtius, J. pr. **146**, 417.

rule the pressure does not materially change during the experiment.

Compounds containing an amino as well as a diazo-group, such as diazoacetamide, may be decomposed by means of dilute hydrochloric acid; after the evolution of nitrogen is completed the ammonium chloride in the flask c may be precipitated with platinum chloride and the amido and diazo nitrogen thus separately determined in one operation.

(B) Aromatic Diazo Compounds. (Diazonium Derivatives C.N.OH)
$$\overset{\text{III}}{N}$$

The diazo group in aromatic compounds is usually determined by the preceding method [1] (3), but it is preferable to employ a Lunge's nitrometer and 40 per cent sulphuric acid.[2] If the compound is unstable and the determination is made in a current of carbonic anhydride[3] the air should be expelled at a temperature of $0°$.[4] Sulphuric acid, sp. gr. $= 1.306$, has a vapor tension of 9.4 mm at $15°$.[5]

DETERMINATION OF THE HYDRAZIDE GROUP
$$(\overset{\text{l}}{N}H.NH_2).$$

Either the oxidation or iodometric method may be employed.

(1) OXIDATION OF HYDRAZIDES.[1]

Boiling Fehling's solution hydrolyses acid hydrazides, and oxidizes the resulting phenyl hydrazine, the nitrogen of which is evolved quantitatively and determined by the method described on p. 65. The compound is dissolved if possible in water or alcohol; hydrazides which do not dissolve are weighed into a small stoppered vessel which is fixed mouth downwards in the hole of the stopper otherwise occupied by the funnel A, Fig. 8, and is dropped into the boiling solution by means of a glass rod of the same volume. Insoluble compounds may also be treated according to the following method:[2] 100 cc Fehling's solution and 150 cc alcohol, together with a few fragments of porcelain, are placed in a 500 cc flask fitted with a doubly bored rubber stopper. In the one hole the tube containing the weighed substance is placed, whilst through the other passes the end of an inclined condenser. The contents of the flask are boiled and the open end of the condenser connected with a bent tube terminating in a short leg which dips below water. When no more air is expelled a measuring vessel full of water is placed over the end of the tube, and the vessel with the substance pressed into the flask by means of a rod. Continued boiling for a short time suffices to liberate all the nitrogen.

[2] H. Meyer, M. 18, 404.

In some cases it is desirable to recover the acid on account of its rarity, or to remove it in order to facilitate the determination, as in the case of stearic acid, the potassium salt of which causes the liquid to froth over. This can be accomplished, if the acid is sparingly soluble in water or dilute hydrochloric acid, by boiling the hydrazide with concentrated hydrochloric acid, during several hours; the solution is made up to 100 cc, the organic acid removed by means of a dry filter, the first few drops of the filtrate rejected, and 50 cc of the remainder taken for the determination. This method of hydrolysis does not distinguish between hydrazides and hydrazones, as the latter are also acted upon by hydrochloric acid. Ortho- and paratolylhydrazides are oxidized in the same manner as phenylhydrazides, so that the method is also applicable to them.[1]

Platinic chloride oxidizes hydrazine hydrochloride in accordance with the equation:

$$N_2H_4.2HCl + 2PtCl_4 \longrightarrow N_2 + 6HCl + 2PtCl_2;$$
the evolved nitrogen is determined by the method described on p. 101.[2]

Hydrazine salts may be titrated by potassium permanganate in presence of sulphuric acid, provided the concentration of the latter is 6–12 per cent.[3] The reaction is represented by the equation

$$17N_2H_4 + 13O \longrightarrow 13H_2O + 14NH_3 + 10N_2.$$

(2) IODOMETRIC METHOD.[1]

Phenylhydrazine and iodine react in accordance with the following equation:

$$C_6H_5NH.NH_2 + 2I_2 \longrightarrow 3HI + N_2 + C_6H_5I.$$
The interaction is quantitative in highly dilute solution with iodine present in excess. The determination is made by adding to a known volume of N/10 iodine solution the highly dilute solution of the base or its hydrochloride, obtained by hydrolysis as described in the preceding section; the excess of iodine is then titrated in the ordinary manner.

In presence of dilute sulphuric acid iodic acid oxidizes phenylhydrazine and this reaction may also be employed for the determination. The strength of the iodic acid solution is ascertained by means of sulphurous acid of known titre; it is then added, in excess, to the highly dilute solution of phenyl-hydrazine and sulphuric acid, and the mixture again titrated.

To the above methods may be added the *titration* of phenylhydrazine with hydrochloric acid; methylorange is used as indicator, and tolerably accurate results are obtained.[2]

DETERMINATION OF THE NITRO-GROUP $(\overset{1}{N}O_2)$.

(A) Titration Method.[3]

Organic nitro-compounds are reduced to amino-derivatives by the action of stannous chloride, in

---

[1] E. v. Meyer, J. pr. 149, 115.　　[2] Strache and Iritzer.
[3] H. Limpricht, B. 11, 35.

presence of hydrochloric acid, in accordance with the equation

$$R.NO_2 + 3SnCl_2 + 6HCl \rightarrow R.NH_2 + 3SnCl_4 + 2H_2O;$$
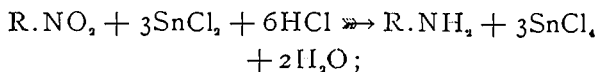

the unchanged stannous chloride is determined by titration, and, from the quantity which has reacted, the number of nitro-groups in the original compound may be ascertained, Solution of iodine, or of potassium permanganate, is employed for the titration.[1]

Reagents Required.

(1) *Stannous Chloride Solution.* Tin (150 grams) is dissolved in concentrated hydrochloric acid, the clear liquid decanted, mixed with concentrated hydrochloric acid (50 cc), and diluted to 1 liter.

(2) *Sodium Carbonate Solution.* Anhydrous sodium carbonate (180 grams) and sodium potassium tartrate (240 grams) are dissolved in water and diluted to 1 liter.

(3) *Iodine Solution.* Iodine (12.54 grams) is dissolved in potassium iodide solution and the liquid made up to 1 liter, it will then be approximately N/10, if exactly so 1 cc = 0.0059 gram Sn = 0.000 655 gram NO_2.

(4) *Starch Solution.* This must be dilute, recently prepared, and filtered.

Potassium Permanganate Solution. It should be

---

[1] Jenssen, J. pr. **78**, 193.   S. W. Young and R. E. Swain, J. Am. (1897), **19**, 812-814. Journ. Chem. Soc. (1898), **74**, ii, 186.

N/10, and may be used instead of the iodine, its strength being determined by means of iron.

(I) *Method of Determination for Non-volatile Compounds.*

After the titre of the stannous chloride has been ascertained, the nitro-compound (about 0.2 gram) is placed in a 100 cc glass-stoppered flask, stannous chloride solution (10 cc) added, and the liquid warmed during thirty minutes. When cool, the mixture is diluted to the mark, and, after shaking, 10 cc transferred to a beaker by means of a pipette; a little water is added, then the sodium carbonate solution, until the precipitate which first forms is wholly dissolved; after the addition of a little starch the iodine solution is run in until a permanent blue coloration is produced.

The results of the analysis are calculated according to the formula $NO_2 = (a - b).0.0007655$ gram, where $a =$ the number of cc of iodine solution equivalent to 1 cc of the stannous chloride solution, and $b =$ the number of cc of iodine solution required in the determination.

If it is desired to use the potassium permanganate 10 cc of the acid liquid, withdrawn as described above, is boiled with ferric chloride, and the ferrous chloride produced is determined in the ordinary manner.

(II) *Modified Method for Volatile Compounds.*

Volatile nitro-compounds are weighed in a test-tube about 30 cm by 8 mm, closed with a cork; the cork is removed, and the tube, together with the stannous

chloride, placed in a second larger one, 20 cm by 13–15 mm, which is then sealed. The larger tube may be of thin-walled, readily fusible glass, as it will only be subjected to a very slight pressure. The tube is heated in the water-bath during 1–2 hours, and well shaken occasionally; it is then cooled, the contents completely washed into a 100-cc graduated flask, and treated in the manner described in the preceding section. The use of a sealed tube is sometimes advisable in the case of non-volatile compounds with which low results may be obtained by heating in the stoppered bottle.

(B) Diazo Method.[1]

Should the preceding method fail to give decisive results the nitro-compound must be reduced to the amino-derivative and this treated in the manner described on p. 87. As an example metanitrobenzaldehyde may be converted into metachlorobenzaldehyde at one operation.[2] It is dissolved in concentrated hydrochloric acid (6 parts), stannous chloride (4.5 parts) added, and after the reduction, without precipitating the tin, it is mixed with the calculated quantity of sodium nitrite and an equal weight of finely divided copper.

DETERMINATION OF THE IODOSO- (IO) AND IODOXY- (IO$_2$) GROUPS.

Iodoso- and iodoxy-compounds in presence of glacial acetic, of hydrochloric acid, or of dilute sulphuric acid liberate from potassium iodide an amount

---

[1] Gattermann, B. 23, 1222.   [2] Gattermann, loc. cit.

of iodine equivalent to their content of oxygen; one molecule of the former therefore liberates two, and of the latter four atoms of iodine. For the determination the substance is heated on the water-bath during four hours with acidified potassium iodide solution in a sealed tube from which the air has been expelled by carbonic anhydride.[1] The compound may also be digested on the water-bath with concentrated potassium iodide solution, glacial acetic acid, in fairly large quantity, and dilute sulphuric acid.[2] When the reaction is completed the liquid is titrated with N/10 sodium thiosulphate solution; no indicator is required. Whenever hydrochloric acid or sulphuric acid has been employed in the reduction, the iodide, which is produced, always retains some iodine in solution hence, during the titration, it is necessary to warm and shake the liquid until this has all been acted upon by the thiosulphate. The oxygen percentage content of the iodosy- and iodoxy-compounds is given by the formula $O = \dfrac{0.8 . c . 100}{1000 \, s} = 0.08 \dfrac{c}{s}$, where s is the weight of the compound taken and c the number of cc of N/10 sodium thiosulphate employed.

DETERMINATION OF THE PEROXIDE GROUP $\left(C \!\! \begin{array}{c} n \\[-2pt] \diagdown \end{array} \!\!\! \begin{array}{c} O \\[-2pt] O \end{array} \right)$.

The oxygen of the acyl superoxides may be determined by means of stannous chloride in acid solution.

[2] Willgerodt, *Ibid.* 25, 3495, *et seq.*

[3] Pechmann and Vanino, *Ibid.* 27, 1512.

A known quantity of the peroxide is heated during about five minutes, in an atmosphere of carbonic anhydride, with a measured volume of a titrated, acidified stannous chloride solution. When the liquid is clear the remaining stannous chloride is determined by means of N/10 iodine solution.

THE IODINE NUMBER.[1]

This value expresses the quantity of iodine absorbed by one hundred parts of the substance, usually a fat or higher aliphatic acid. The acids of this series, such as oleic acid, ricinoleic acid, linoleic acid and linolenic acid, as well as their glycerides, absorb the first two, two, the others four and six atoms of iodine, bromine, or chlorine respectively, whilst the corresponding saturated compounds, under similar circumstances, are not affected. The reaction is carried out at the ordinary temperature, the substance being mixed with alcoholic iodine and mercuric chloride solutions.[2] The organic products are chloro-iodine additive compounds, some of which have been isolated and characterized.[3] The method is extensively employed in the technical investigation of fats, oils, waxes, resins, etheral oils, caoutchouc, etc., and is sometimes useful for scientific purposes, hence a brief description of the method of analysis is given here.

[2] Hübl, Dingl. **253**, 281.

[3] R. Henriques and H. Künne. B. **32**, 389.

Reagents.

(1) *Iodine Solution.* Iodine (25 grams) and mercuric chloride (30 grams) are each separately dissolved in 95 per cent alcohol (500 cc), free from fusel oil. The mercuric chloride solution is filtered if necessary, and the liquids mixed. The mixing must precede the use of the solution by 6–12 hours as, during this period, the titre rapidly changes.

(2) *Sodium Thiosulphate Solution.* The crystallized salt (24 grams) is dissolved in water and diluted to one liter. It is standardized in the following manner: Potassium bichromate (3.8740 grams) is dissolved in water, diluted to one liter, and 20 cc of the liquid transferred to a stoppered bottle containing 10 cc of potassium iodide solution (10 per cent), and 5 cc hydrochloric acid; the liberated iodine is then titrated in the ordinary manner by means of sodium thiosulphate, starch being used as indicator; 1 cc of the above bichromate solution liberates 0.01 grams of iodine.

(3) *Chloroform.* Its purity is determined by a blank experiment.

(4) *Potassium Iodide Solution.* The salt is dissolved in ten parts of water.

(5) *Starch Solution.* This must be clear and recently prepared.

Method of Analysis.

The substance (0.15–1.0 gram) is mixed with chloroform (about 10 cc) in a 500–800 cc flask provided with

a well-fitting glass-stopper. When the compound has dissolved the iodine solution (25 cc) is added by means of a pipette which must be manipulated so that equal quantities are delivered in each experiment. The flask is well shaken and more chloroform added if needful; should the liquid become almost colorless in a short time a second 25 cc of iodine solution is added, and this repeated, if necessary until, after the expiration of two hours, the liquid appears dark brown. The mixture is now allowed to remain during twelve hours at the ordinary temperature in the dark; it is then thoroughly mixed with at least 20 cc of potassium iodide solution and 300–500 cc of water, and titrated with the sodium thiosulphate solution, the liquid being constantly agitated; when only a faint color is visible in both the aqueous and chloroform solutions, starch is added and the titration completed. The production of a red precipitate of mercuric iodide, on the addition of water before the titration, indicates that too little potassium iodine has been employed, but this may be corrected by the immediate addition of more. A blank experiment must always be made with 25 cc of the iodine solution under exactly the same conditions as the test, and its titration must immediately precede or follow that of the actual determination.

Useful information is sometimes given by the *terebenthene number*.[1]
